A semi-physical model based on standard meteorological data is developed to estimate solar radiation received at the Earth's surface. The radiation model includes the effects of Rayleigh scattering, absorption by water vapor and permanent gases, and absorption and scattering by aerosols and clouds. Cloud attenuation is accounted for by assigning transmission coefficients based on cloud height and amount. The cloud transmission coefficients for various heights and coverages were derived empirically from hourly observations of solar radiation in conjunction with corresponding cloud observations at West Lafayette, Indiana. The model was tested with independent data from twelve North American sites. (19 refs.)

110538 An intercomparison between radiation budget estimates from METEOSAT 1, Nimbus 7 and TIROS-N satellites. R.W.Saunders (Dept. of Phys. & Astron., Univ. Coll. London, London, England), L.L.Stowe, G.E.Hunt, C.F.England.
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.546-59 (April 1983).
Daily averaged and instantaneous values of the Earth's radiation budget have been computed from the satellite measurements of reflected solar and emitted terrestrial radiation with METEOSAT 1, Nimbus 7 ERB and TIROS-N scanning radiometers. The estimates have been compared for 12 selected 2.5°×2.5° latitude-longitude regions for 14 October 1979. The comparisons between the three independent data sets is discussed and an assessment is made of the relative importance of diurnal variations and anisotropic scattering models. (29 refs.)

110539 An analysis of the ground temperature and reflectivity pattern about St. Louis, Missouri, using HCMM satellite data. F.M.Vukovich (Research Triangle Inst., Research Triangle Park, NC, USA).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.560-71 (April 1983).
Analyses demonstrate marked seasonal and day/night differences. The temperature contrast between the urban and rural region averages about 4.3C°. Difference in reflectivity between the centre of St. Louis and the surrounding suburban and rural regions ranges from 2 to 4 percentage points. (30 refs.)

110540 A model for the Priestley-Taylor parameter α. H.A.R.de Bruin (Royal Netherlands Meteorological Inst., De Bilt, Netherlands).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.572-8 (April 1983).
The behaviour of the Priestley-Taylor parameter α is investigated using a simplified atmospheric boundary-layer model coupled to the Penman-Monteith equation. It is found that under conditions typical for a sunny summer day in the mid-latitudes, α is primarily determined by the surface resistance r_s ($\alpha \approx 1.3$ when $r_s = 0$, $\alpha \approx 1$ when $r_s \approx 60$ s m^{-1}, and $\alpha \approx 0.6$ when $r_s \approx 250$ s m^{-1}). This is in good agreement with experimental values reported in literature. The model is an extension of the models by McNaughton (1976) and Perrier (1980). (17 refs.)

110541 Thunderstorm top structure observed by aircraft overflights with an infrared radiometer. R.F.Adler, M.J.Markus (Goddard Lab. for Atmospheric Sci., NASA/Goddard Space Flight Centre, Greenbelt, MD, USA), D.D.Fenn, G.Szejwzch, W.E.Shenk.
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.579-93 (April 1983).
Thunderstorm top structure is examined with high spatial resolution radiometric data (visible and infrared) from aircraft overflights together with other storm views, including geosynchronous satellite observations. The growth period of a relatively weak cumulonimbus cluster is also examined with aircraft and satellite data. (25 refs.)

110542 Experimental studies of the turbulence structure parameters of the convective boundary layer. A.Druilhet, J.P.Frangi, D.Guedalia, J.Fontan (Lab. de Phys. des Aerosols et Echanges Atmospheriques, Toulouse, France).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.594-608 (April 1983).
Presents a collection of experimental data obtained by means of instrumented aircraft during numerous experiments carried out above five flight areas from 1973 to 1978. Only dry convective conditions with weak dynamic instability are considered. The computed quantities are vertical turbulent fluxes of sensible and latent heat, second- and third-order moments of vertical wind component, potential temperature and humidity, dissipative and spectral characteristics and length scales. All these quantities are normalised using the convective similarity hypothesis of Deardorff. (60 refs.)

110543 Severe storm observations using the microwave sounding unit. N.C.Grody (NOAA/NESDIS, Washington, DC, USA).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.609-25 (April 1983).
The microwave sounding unit (MSU) aboard the NOAA polar orbiting satellites contains four channels in the oxygen band, at 50.30, 53.74, 54.96 and 57.95 GHz, which receive thermal radiation originating primarily from four regions ranging from surface to the lower stratosphere. This study focuses on the measurements obtained for a convective storm over the central United States beginning 12 April 1979. Temperature and precipitation effects are examined by comparing the MSU measurements with 'clear column' brightness temperatures computed from radiosonde data. (18 refs.)

110544 On using historical comparisons in evaluating cloud seeding operations. K.R.Gabriel, D.Petrondas (Dept. of Statistics, Univ. of Rochester, Rochester, NY, USA).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.626-31 (April 1983).
Cloud seeding operations are often evaluated by comparing precipitation during operations with records of previous 'historical' precipitation. Extensive worldwide precipitation records are used to examine whether the usual statistical techniques may be validly applied to comparisons of precipitation in successive years. (8 refs.)

110545 Simulation of transport and removal processes of the Saharan dust. In-Young Lee (Radiological & Environmental Res. Div., Argonne Nat. Lab., Argonne, IL, USA).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.632-9 (April 1983).
A planetary boundary layer model has been modified to include a Saharan air layer containing the bulk of Saharan dust. The Saharan air layer is recognised as a deep mixed layer which extends up to 4-6 km during hot summer months and is characterised by high potential temperature and high dust concentration. Microphysical processes of particle coagulation and sedimentation have been coupled with dynamic processes to simulate the evolution of dust particles. (17 refs.)

110546 Mt. St. Helens' aerosols: some tropospheric and stratospheric effects. J.J.Michalsky, G.M.Stokes (Pacific Northwest Lab., Richland, WA, USA).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.640-8 (April 1983).
Aerosol optical depth measurements based on the attenuation of direct solar radiation before and after the six major explosive eruptions of Mt. St. Helens during 1980 are presented. These automated measurements are from a site 200 km mostly east and slightly north of the volcano. In several cases the conversion of sulphur gases to sulphates proceeded much more rapidly (hours) than is usually found for tropospheric conditions. The second major result was that there was no evidence of a residual aerosol burden. (12 refs.)

110547 The use of high horizontal resolution satellite temperature and moisture profiles to initialise a mesoscale numerical weather prediction model—a severe weather event case study. G.A.Mills (Australian Numerical Meteorological Res. Centre, Melbourne, Australia), C.M.Hayden.
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.649-63 (April 1983).
Describes the assimilation of sub-synoptic resolution satellite-derived temperature and moisture profiles into a mesoscale numerical weather prediction model, intended for forecasting the environment of organised convective storm complexes in the midwest of the United States. It is demonstrated that the use of high resolution satellite data to initialise the system results in a good

level of forecast accuracy for the case study chosen, with very encouraging accuracy in the forecast moisture and vertical motion fields. (33 refs.)

110548 Comparison of tetroon and computed trajectories. L.M.Reisinger, S.F.Mueller (Tennessee Valley Authority, Muscle Shoals, AL, USA).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.664-72 (April 1983).
Forty-five tetroon flights made during the summer of 1980 for the PEPE/NEROS regional pollution studies, sponsored by the US Environmental Protection Agency, were compared to computed trajectories based on National Weather Service rawinsonde wind fields. Most tetroon data were obtained for travel times of less than 10 h and travel distances of less than 150 km. Two trajectory computation algorithms were used. No significant differences were found between the two comparisons. (17 refs.)

110549 Integral scales for the nocturnal boundary layer. I. Empirical depth relationships. R.B.Stull (Dept. of Meteorology, Univ. of Wisconsin, Madison, WI, USA).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.673-86 (April 1983).
The stable-layer thickness and near-surface potential temperature strength of the nocturnal boundary layer (NBL) are shown to have a 'background' square-root of time dependence. Superimposed upon this background are other time variations caused by changes in bulk turbulence parameter B and average surface heat flux. As an intentionally different approach to the NBL problem B is modelled in terms of forcings external to the NBL rather than in terms of internal variables. Nocturnal boundary layer observations from the Wangara and Koorin field experiments in Australia are used to yield B in terms of the geostrophic wind vector, the Coriolis parameter, the acceleration due to gravity, and a site and wind-direction-dependent empirical parameter. The resulting model is shown to be adaptable to frost-warning and air-quality applications. (28 refs.)

110550 Interannual variations of mean monthly sea-level pressure in January. H.van Loon, R.A.Madden (Nat. Centre for Atmospheric Res., Boulder, CO, USA).
J. Clim. & Appl. Meteorol. (USA), vol.22, no.4, p.687-92 (April 1983).
The standard deviations of mean sea-level pressure in January are compared for five discrete 16-year periods between 1901 and 1980. The changes from one period to another are large and larger in the North Atlantic than in the North Pacific Ocean. The differences between the periods are associated with variations in the position and central pressure of the Aleutian and Icelandic lows. There is no consistent link between the two lows as their central pressure varied in parallel till the late 1930s and oppositely thereafter. (9 refs.)

110551 The Group Agromet Monitoring Project (GAMP): application of Meteosat data for rainfall, evaporation, soil-moisture and plant-growth monitoring in Africa. C.E.England (Lab. for Planetary Atmospheres, London, England), R.Gombeer, E.Hechinger, R.W.Herschy, A.Rosema, L.Stroosnijder.
ESA J. (Netherlands), vol.7, no.2, p.169-88 (1983).
Summarises the results of the Group Agromet Monitoring Project which is intended to map and monitor key agro-meteorological parameters in the Sahel of Africa. The physiography and agro-environment of the test area in Mali are described, together with ground-truth and satellite data collection, as well as the geometric and atmospheric correction of the latter. Mapping of rainfall, surface radiation, evaporation and thermal inertia are discussed. A tentative germination-mapping approach is proposed. The results of rainfall, evaporation and germination mapping over the 18d test period are presented and discussed. It is concluded that Meteosat has the ability to provide unique surface climatological data. (4 refs.)

110552 Relationships between macrocirculation atmospheric processes at levels from 10 up to 100 km over middle Asia. K.A.Karimov.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.6, p.563-9 (June 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
Presents variations of daily averaged values of the zonal wind with synoptic periods for the levels from 10 up to 100 km. Using results of radiometeor observations at Frunze during 1970-1980 the author shows a connection of macrocirculation characteristics of the lower thermosphere with similar processes in the meso-and stratosphere. Phase changes of zonal wind temporal variations at tropospheric levels are in the opposite phase with stratospheric processes and in phase with mesospheric processes plus 2π. Using many years of radiometeor wind observations with simultaneous satellite thermal soundings, results of rocket and aerological observations the author proposes and discusses an empirical three-layer model of the atmosphere describing the connection of macrocirculation processes with synoptic periods at altitudes from 10 to 100 km. (11 refs.)

110553 Radar investigation of wind field divergence in convective clouds. A.A.Ivanov, Yu.V.Mel'nichuk, A.K.Morgoev.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.6, p.576-85 (June 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
The experimental results of dual doppler radar investigations of wind field divergence in cumulonimbus clouds are presented. The average relationship between divergence components measured in the horizontal plane is found. The vertical flow speed increments computed from the data of one- and two-dimensional measurements are compared and conclusions are presented on a possibility of using the single doppler radar for wind structure observations in cumulonimbus clouds. (6 refs.)

110554 Electrooptical studies of the humidification processes of different aerosols. V.N.Kapustin, Yu.S.Lyubovtseva, S.P.Stoylov, I.Petkanchin.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.7, p.696-702 (July 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
Results of electrooptical studies of NaCl, KCl and MgO aerosols are presented. It is shown that the particle's degree of orientation depends on the induced and permanent dipole moments associated with the particle. At low relative humidity (RH) the main influence on the orientation of the particle is the permanent dipole moment. With the growth of RH the influence of the induced dipole moment shows a strong increase. The observed changes in the electrical parameters of the particles reflect the physical changes on the particle/air interface that result from adsorption of water vapour. (8 refs.)

110555 The dependence of the *Q*-branch contour of Raman spectra of water vapour on temperature. Yu.S.Georgievskii, A.N.Denisov, V.M.Kopeikin.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.7, p.709-15 (July 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
Theoretical and experimental investigations of the Q-branch contour of Raman spectra dependence on temperature are discussed for water vapour. An analysis is carried out for changes with temperature of the contour for gaussian and triangle aperture functions with widths from 1 to 2 cm^{-1} in the temperature range 0-600°C. A formula is proposed for determination of the water vapour temperature from the ratio of intensities of two peaks of the Q-branch. Temperature ranges are determined in which one can control the water vapour concentration independently of temperature by the intensity of one of the peaks. An analysis of factors influencing the accuracy of temperature determinations is carried out and the corresponding errors are estimated. (18 refs.)

110556 Microwave attenuation statistics due to rain along Earth-space path. R.Chadha, G.S.Uppal, M.K.Raina (Radio Sci. Div., Nat. Phys. Lab., New Delhi, India).
Indian J. Radio & Space Phys., vol.12, no.2, p.37-9 (April 1983).
The rain attenuation statistics at 11 and 18 GHz derived from measurements by using microwave radiometers at 11 and 18 GHz over New Delhi are described. The worst month is determined from the cumulative distribution to be Aug. 1978. Rainfall and attenuation during the period Sept.-Nov. 1977 is compared to the winter period Dec. 1977-Mar. 1978. Comparison has also been made between the measured attenuation statistics and attenuation statistics obtained using radiometric techniques and direct satellite measurements at different places around the world. (5 refs.)

110557 Barotropic wave propagation and instability, and atmospheric teleconnection patterns. A.J.Simmons (European Centre for Medium Range Weather Forecasts, Reading, England), J.M.Wallace, G.W.Branstator.
J. Atmos. Sci. (USA), vol.40, no.6, p.1363-92 (June 1983).
A global barotropic model, linearized about the 300 mb climatological mean January flow, is perturbed by applying a series of localized forcings distributed throughout the tropics and subtropics. Structures which resemble the observed 'Pacific/North American' and 'East Atlantic' teleconnection patterns noted by Wallace and Gutzler (1981) tend to recur in the responses. Similar patterns are found to result from the dispersion of isolated initial perturbations placed at a variety of locations in the tropics and midlatitudes. It is shown that these structures are related to the most rapidly growing mode associated with barotropic instability of the zonally-varying climatological basic state. In the absence of damping, this mode has an e-folding time of about a week and a period close to 50 days. (51 refs.)

110558 The Charney baroclinic stability problem: approximate solutions and modal structures. L.E.Branscome (Rosenstiel School of Marine & Atmospheric Sci., Univ. of Miami, Miami, FL, USA).
J. Atmos. Sci. (USA), vol.40, no.6, p.1393-409 (June 1983).
The classic Charney baroclinic stability problem is examined through perturbation techniques in the shortwave limit, near the first neutral curve separating Charney and Green modes, and near the second neutral curve separating long and short Green modes. This method provides simple analytical expressions for the vertical structure of the growing waves and the dependence of phase speeds and growth rates on mean flow parameters. The rapidly growing Charney modes have horizontal and vertical scales which crucially depend on the β-parameter. Structures and heat and potential vorticity fluxes are also represented by approximate solutions and their dependence on wavenumber is examined. (25 refs.)

110559 The dynamical structure of the planetary boundary layer over the Arabian Sea, as deduced from constant-level balloon trajectories. G.Reverdin, G.Sommeria (Lab. de Meteorologie Dynamique, Paris, France).
J. Atmos. Sci. (USA), vol.40, no.6, p.1435-52 (June 1983).
During Summer 1979, 88 super-pressure constant-level balloons were launched at the nominal flight level of 900 mb from the Seychelles Islands and from the northern tip of the Malagasy Republic as part of the French participation in the MONEX experiment. Balloons tracked by the Argos system onboard TIROS-N and NOAA-6 satellites provide good estimates of the wind velocity and of the Lagrangian acceleration of air masses within the planetary boundary layer. With additional wind and pressure data, a study of the balance of forces and of the vertical wind structure in the planetary boundary layer has been performed, including the computation of the vertical transport of horizontal momentum by turbulent mixing. (19 refs.)

110560 Boundary layer evolution in the region between shore and cloud edge during cold-air outbreaks. S.A.Stage (Dept. of Meteorology, Florida State Univ., Tallahassee, FL, USA).
J. Atmos. Sci. (USA), vol.40, no.6, p.1453-71 (June 1983).
Equations for the evolution of the atmospheric boundary layer during cold air outbreaks are examined and analytic solutions are obtained which apply to the region prior to cloud formation whenever the soundings of potential temperature and water vapor mixing ratio at the shore may be treated as linear. The solutions have non-dimensionalized boundary layer depth as the independent parameter. Layer depth, potential temperature, mixing ratio, dewpoint, lifting condensation level, distance from shore (fetch), net sensible heat input, and net latent heat input are found as explicit functions of a nondimensional mixed-layer height. A perturbation method is used to derive solutions when divergence is significant and is shown to be a good approximation for realistically strong divergences. (9 refs.)

110561 The adequacy of the hydrostatic assumption in sea breeze modeling over flat terrain. C.L.Martin (Simpson Weather Associates, Charlottesville, VA, USA), R.A.Pielke.
J. Atmos. Sci. (USA), vol.40, no.6, p.1472-81 (June 1983).
Using a linear analytic model and a nonlinear numerical model, the adequacy of the hydrostatic model is investigated for use in the simulation of sea and land breezes over flat terrain. Among the results it is found that for a given horizontal scale of heating, the hydrostatic assumption becomes less valid as the intensity of surface heating increases, and as the synoptic temperature lapse rate becomes less stable. The spatial scale at which the hydrostatic assumption fails is substantially smaller than suggested by Orlanski (1981). For sufficiently stable large-scale thermodynamic stratifications, for instance, aspect ratios of order unity can still produce nearly identical solutions, regardless of whether or not the hydrostatic assumption is used. (9 refs.)

110562 Case study of a hailstorm in Colorado. IV. Graupel and hail growth mechanisms deduced through particle trajectory calculations. A.J.Heymsfield (Nat. Center for Atmospheric Res., Boulder, CO, USA).
J. Atmos. Sci. (USA), vol.40, no.6, p.1482-509 (June 1983).
For pt.III see ibid., vol.40, no.3, p.686-707 (1983). The processes of development of graupel and hail which fell to the ground from a storm in northeastern Colorado on 22 July 1976 are investigated over a one-hour period. The growth and trajectories of 130000 particles of different types and sizes are calculated in the measured three-dimensional wind fields. The growth conditions that these graupel and hail (spherical ice particles smaller than and larger than 1 cm, respectively) experience are presented and their trajectories are described. Particles which become hail are those whose terminal velocities are nearly equal to the vertical velocities of the air parcels in which they develop. (18 refs.)

110563 Measurement and interpretation of hailstone density and terminal velocity. N.C.Knight, A.J.Heymsfield (Nat. Center for Atmospheric Res., Boulder, CO, USA).
J. Atmos. Sci. (USA), vol.40, no.6, p.1510-16 (June 1983).
The mass, density, fall velocity and internal structure have been determined for low-density hailstones from an early spring storm in Boulder, Colorado, and drag coefficients were calculated. The density of the permeable hail is determined from a new method of volume measurement. The results are compared to those of particles grown in a one-dimensional parcel model using the appropriate sounding. The implications of the results are discussed with reference to hail growth in convective storms. (15 refs.)

110564 The role of cloud top entrainment in cumulus clouds. J.F.Boatman, A.H.Auer (Dept. of Atmospheric Sci., Univ. of Wyoming, Laramie, WY, USA).
J. Atmos. Sci. (USA), vol.40, no.6, p.1517-34 (June 1983).
This research was undertaken to discover the role which cloud top plays in the entrainment process and to determine whether observed downdraft magnitudes could be explained on the basis of evaporative cooling. An instrumented King Air research aircraft was used to acquire thermodynamic, microphysical and dynamical data within and near cumulus clouds of the high plains and midwestern United States. Temperature and liquid water content measurements made within the clouds were used to discover the source for any entrained air via a thermodynamic treatment initially pursued by Dufour (1956), and later expanded by Paluch (1979) and Betts (1982). The entrainment source regions found were either at or above the aircraft sampling level in 78 of the 87 cases examined. It was concluded that evaporative cooling could adequately explain the magnitude of the observed downdrafts in the 51 cases where a comparison between the predicted and observed downdraft magnitude was possible. (27 refs.)

110565 Numerical studies of major and minor stratospheric warmings caused by orographic forcing. J.P.Koermer, A.Kasahara, S.K.Kao (Dept. of Meteorology, Univ. of Utah, Salt Lake City, UT, USA).
J. Atmos. Sci. (USA), vol.40, no.6, p.1552-70 (June 1983).
A primitive equation spectral model using spherical harmonics is formulated to study dynamic interactions between the troposphere and stratosphere in association with sudden stratospheric warmings. Using sigma coordinates for five tropospheric layers and log-pressure coordinates for 26 stratospheric and mesospheric layers, separate model equations for each system are combined to form single matrix governing equations. The gradual introduction of large scale topography to balanced initial states representative of observed mean winter conditions in the Northern Hemisphere is used for the generation of planetary waves during 40-day time integrations. (50 refs.)

110566 Transformed Eliassen balanced vortex model. W.H.Schubert (Dept. of Atmospheric Sci., Colorado State Univ., Fort Collins, CO, USA), J.J.Hack.
J. Atmos. Sci. (USA), vol.40, no.6, p.1571-83 (June 1983).
Considers the axisymmetric balanced flow occurring in a thermally forced vortex in which the frictional inflow is confined to a thin boundary layer. Above the boundary layer the absolute angular momentum ${}^{1}/_{2}fR^{2}=rv+{}^{1}/_{2}fr^{2}$ is conserved. R is referred to as the potential radius, i.e. the radius to which a particle must be moved (conserving absolute angular momentum) in order to change its tangential component v to zero. Using R as one of the dependent variables the equations of the Eliassen balanced vortex model are then reviewed. The roles of the actual radius r and the potential radius R are then reversed i.e. R is treated as an independent variable and r as a dependent variable. Introducing transformed components (u^{*}, w^{*}) of the transverse circulation the transformed Eliassen balanced vortex equations are then obtained. These differ from the original equations in several respects. (26 refs.)

110567 The latitude-height structure of 40-50 day variations in atmospheric angular momentum. J.R.Anderson (Dept. of Meteorology & Phys. Oceanography, MIT, Cambridge, MA, USA), R.D.Rosen.
J. Atmos. Sci. (USA), vol.40, no.6, p.1584-91 (June 1983).
Quasiperiodic variations in the relative angular momentum of the atmosphere on time scales of around 40-50 days have been observed by Langley et al. (1981). A description of the two-dimensional (latitude-height) structure of the winds responsible for these changes is constructed in this article from five years of NMC twice-daily global analyses. Using cross-spectral and amplitude-phase eigenvector techniques, the authors find these variations are associated with wavelike motions in the tropical upper troposphere that propagate poleward and downward in phase within the tropics. A coherently connected midlatitude Northern Hemisphere component is also present whose phase is essentially independent of height. The tropical component is believed to be the zonally averaged part of the motions described by Madden and Julian (1971, 1972). (22 refs.)

110568 A model of the atmospheric boundary layer over the marginal ice zone. J.E.Overland, R.M.Reynolds, C.H.Pease (Pacific Marine Environmental Lab./NOAA, Seattle, WA, USA).
J. Geophys. Res. (USA), vol.88, no.C5, p.2836-40 (30 March 1983). [received: Sept. 1983]
A one-layer, primitive equation model is presented for the atmospheric boundary layer over the marginal ice zone (MIZ). The model simulates the slow rate of inversion growth and rate of warming of the boundary layer seaward of an ice edge for off-ice winds observed on two cruises in the Bering Sea by the NOAA R/V Surveyor. The horizontal temperature gradient in the boundary layer, caused by the oceanic heat flux seaward of an ice edge, induced an increase in wind speed with a maximum increase of 8% at 50 km seaward of the edge. At 100 km off ice, a momentum balance is established between accelerative terms and decelerative terms. Wind velocity in the boundary layer over the MIZ during off-ice winds is sensitive to changes in surface roughness. (22 refs.)

110569 Electron energy deposition in the middle atmosphere. A.L.Vampola, D.J.Gorney (Space Sci. Lab., Aerospace Corp., Los Angeles, CA, USA).
J. Geophys. Res. (USA), vol.88, no.A8, p.6267-74 (1 Aug. 1983).
Spectra of locally precipitating 36- to 317-keV electrons obtained by instrumentation on the S3-2 satellite are used to calculate energy deposition profiles as a function of latitude, longitude and altitude. In the 70- to 90-km altitude, mid-latitude ionization due to these precipitating energetic electrons can be comparable to that due to direct solar H Lyman α. At night, the electrons produce ionization more than an order of magnitude greater than that expected from scattered H Lyman α. Maximum precipitation rates in the region of the South Atlantic Anomaly are of the order of 10^{-2} erg/cm^{2} s with a spectrum of the form $j(E)=1.34\times10^{5}\ E^{-2.27}$ (keV). (39 refs.)

110570 A comparison between computed and measured oceanic winds near the British Columbia coast. R.E.Thomson (Inst. of Ocean Sci., Sidney, BC, Canada).
J. Geophys. Res. (USA), vol.88, no.C4, p.2675-83 (20 March 1983). [received: Sept. 1983]
Winds measured over the continental shelf off Vancouver Island during the summers of 1979 and 1980 are compared with winds computed by the National Marine Fisheries Service (Monterey, California), using synoptic surface atmospheric pressures. Although there is considerable qualitative similarity between the two sets of data, the computer 6-hourly winds fail accurately to resolve short-period fluctuations associated with transient wind systems and tend to underestimate the percentages of time of low and high wind speeds. In the frequency domain, the computed winds are representative to the oceanic winds for periods exceeding roughly 2 days but only marginally representative for periods of $1^{1}/_{2}$-2 days. At periods less than about $1^{1}/_{2}$ days, computed winds are not reliable indicators of oceanic wind variability. Moreover, the computed winds possess a large-amplitude sea breeze (diurnal) component that is present in the inner shelf wind data but not in the outer shelf wind data. (11 refs.)

110571 The influence of the Antarctic Peninsula on the wind field over the western Weddell Sea. T.R.Parish (Dept. of Atmospheric Sci., Univ. of Wyoming, Laramie, WY, USA).
J. Geophys. Res. (USA), vol.88, no.C4, p.2684-92 (20 March 1983). [received: Sept. 1983]
The Antarctic Peninsula is a formidable barrier to the easterly flow of stable air over the Weddell Sea. The damming up of cold stable air against the peninsula mountains creates a pressure field which provides the necessary dynamic support for strong, mountain-parallel winds often observed along the east side. Numerical experiments, using a two-dimensional (x,z) primitive equation model incorporating a cross section of the terrain of the Antarctic Peninsula, are carried out in attempt to simulate the principle features of these barrier winds. Implications of the wind field are discussed. (16 refs.)

110572 Eclipse-related measurements of middle-atmosphere electrical parameters. J.D.Mitchell, L.C.Hale, C.L.Croskey (Electrical Engng. Dept., Pennsylvania State Univ., University Park, PA, USA), R.O.Olsen.
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.515-25 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
Measurements of electrical conductivity and its constituent parameters, charge density and ion mobility, are presented for the solar eclipse rocket campaign conducted at Red Lake, Ontario, Canada. Three parachute-borne probes (two Gerdien condensers and a blunt probe) were flown during the eclipse which occurred on 26 February 1979. Addtitional payloads launched at other times provided important supplemental background measurements. The entire launch series occurred during aurorally active conditions. Specifically, positive conductivity enhancements above 45 km demonstrate the dominance of auroral ionization as a source for positive ions in the region. Such effects evidenced during the eclipse make it difficult to determine the extent to which the decrease in positive conductivity above 60 km is eclipse-related. (27 refs.)

110573 Recent measurements of electrical conductivity and ion pair production rate, and the ion-ion recombination coefficient derived from them in the lower stratosphere. Y.Morita (Res. Inst. of Atmospherics, Nagoya Univ., Toyokawa, Japan).
J. Geomagn. & Geoelectr. (Japan), vol.35, no.2, p.29-38 (1983).
The results of balloon measurements of electrical conductivity and ion pair production rate obtained from the Atmospheric Electrical Measurements Workshop at the University of Wyoming in the summer of 1978 are presented. Reasonable agreement is obtained from comparing the flights for electrical conductivity measurements. A small difference in the compared measurements of ion pair production rate is found at stratospheric heights. The profiles of ion pair production rate measured during the period of different sunspot numbers show a marked dependence of ion pair production rate on solar activity. (26 refs.)

110574 Atmospheric-pollution monitoring through conductivity measurements.. M.Carlevaro (Istituto di Elettrotechnica, Facolta di Ingegneria, Univ. di L'Aquila, L'Aquila, Italy), D.Paloetti.
Lett. Nuovo Cimento (Italy), vol.37, ser.2, no.15, p.539-43 (13 Aug. 1983).
The possibility to correlate the density of gaseous pollutants in the atmosphere (SO_2, NO_x) and the state of air ionization, defined by the volumetric density of ions of different sizes and mobilities has been experimentally investigated. A description is given of a possible method of measurement of atmospheric pollution, based on such a correlation. Preliminary experiments are reported. (3 refs.)

110575 Meteorology and crop-spraying. N.Thompson (Meteorological Office, Bracknell, England).
Meteorol. Mag. (GB), vol.112, no.1333, p.249-60 (Aug. 1983).
Adverse weather can seriously degrade the effectiveness and safety of crop-spraying and, in particular, may lead to damaging spray drift. The author provides a brief review of meteorological factors of importance in crop-spraying, and gives quantitative descriptions of spray drift and the related off-target uptake and deposition of pesticides in both vapour and drop forms. (24 refs.)

110576 Concorde forecasts and the new 15-level model. N.J.Atkins (Meteorological Office, Bracknell, England).
Meteorol. Mag. (GB), vol.112, no.1333, p.261-5 (Aug. 1983).
A global 15-level numerical model recently replaced the 10-level model at Bracknell and its behaviour in relation to the preparation of 100 mb flight forecast charts for Concorde aircraft has been monitored. Results so far are favourable, although a few dynamical problems have emerged. (2 refs.)

110577 Constructing a flow model with accurate satisfaction of the boundary conditions at a cylindrical profile. V.N.Kozhevnikov, A.S.Losev (Dept. of Atmospheric Phys., Moscow Univ., Moscow, USSR).
Moscow Univ. Phys. Bull. (USA), vol.37, no.5, p.48-55 (1982). Translation of: *Vestn. Mosk. Univ. Ser. 3 (USSR)*, vol.37, no.5, p.43-50 (1982).
The question of accurately taking account of the real extended relief into account in the two-dimensional flow problem (in a vertical plane) is considered. The algorithm constructed may also be used in other theoretical models. It is shown, in several examples of calculations for real mountains, that in the flow problem sufficient accuracy is necessary both in taking account of the lower boundary condition and in calculating the trajectories of motion. Calculations show that the perturbations are intense immediately above the mountains, and are almost degenerate in the leeward direction. (12 refs.)

110578 Dispersion limitations of oxidation in power plant plumes during long-range transport. A.T.Cocks, A.S.Kallend, A.R.W.Marsh (Central Electricity Res. Labs., CEGB, Leatherhead, England).
Nature (GB), vol.305, no.5930, p.122-3 (8 Sept. 1983).
During the atmospheric transport of combustion-generated emissions of SO_2 and NO from point sources, the kinetics of oxidation processes are of particular importance in determining the pattern of subsequent wet and dry deposition because oxidation products such as sulphate aerosol and nitric acid may have deposition characteristics totally different from those of primary emissions. The authors report results of measurements made by an instrumented aircraft of the chemistry within a labelled plume on a trajectory over the North Sea which indicate that oxidation of plume material may be limited by dispersion at distances of at least 650 km. (10 refs.)

110579 Upper stratospheric circulations in the two hemispheres observed by satellites. I.Hirota, T.Hirooka, M.Shiotani (Geophys. Inst., Kyoto Univ., Kyoto, Japan).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.443-54 (July 1983).
A global analysis is made of upper stratospheric circulations with the aid of Nimbus 5 and Tiros N satellite observations in order to make a comparison of characteristics between the northern hemisphere (NH) and the southern hemisphere (SH). It is shown that the reversal of north-south gradient of the zonal mean temperature at the stratopause level is always observed in the higher latitudes of the SH winter, while the temperature gradient of the NH winter is variable because of the occurrence of sudden warmings. Consequently, due to the thermal wind relation, the polar night westerlies of the SH stratosphere are generally stronger than those of the NH stratosphere. In association with this difference, the activity of transient planetary waves of wavenumber 2 is striking in the SH, in contrast to the predominance of steady waves in the NH. (22 refs.)

110580 The steady, linear response of the stratosphere to tropospheric forcing. D.J.Karoly, B.J.Hoskins (Dept. of Meteorology, Univ. of Reading, Reading, England).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.455-78 (July 1983).
A linearized, steady-state, 15-level numerical model is used to study the stationary planetary wave response of the stratosphere to thermal and orographic forcing in the troposphere. Zonally symmetric basic states representative of northern hemisphere winter and summer conditions are used. Solutions for each zonal wavenumber are considered separately. Eliassen-Palm cross-sections are used as a diagnostic of wave propagation. First, several simple thermal and orographic forcing distributions are used in the winter basic state. The response in the stratosphere is sensitive to changes in the zonal wind but its structure is insensitive to the forcing mechanism and to the dissipation used in the model. For representative northern hemisphere thermal and orographic forcing, solutions in winter agree well with observations except for wavenumber one, which has too small an amplitude and an incorrect structure. (32 refs.)

110581 A spectral model of the zonally averaged circulation in the middle atmosphere. H.Volland (Radioastronomical Inst., Univ. of Bonn, Bonn, Germany).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.479-99 (July 1983).
Most papers dealing with numerical simulation of the zonally averaged atmospheric circulation start with the solar heat input as an external source that drives the circulation. In this paper, the reverse way will be followed. First, the meridional structure of the wave modes with zonal wavenumber $m=0$ within the atmospheric waveguide is determined from tidal theory. Then the height structure of these modes is calculated numerically applying heat source configuration per mode by trial and error such that the observed global zonal wind and temperature fields between 0 and 100 km can be reproduced reasonably well. (25 refs.)

110582 Simulation of the atmospheric response to soil moisture anomalies over Europe. P.R.Rowntree, J.A.Bolton (Meteorological Office, Bracknell, England).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.501-26 (July 1983).
Positive and negative anomalies in the initial soil moisture over central Europe were introduced in turn into integrations of a global model of the July atmosphere. The results show that by modifying the partitioning of the turbulent fluxes such anomalies can have major effects on the modelled rainfall, humidity and temperature during the following 50 days over the anomaly area and that the anomalies can propagate into adjacent land areas. Similar results were obtained with a lower-resolution version of the model. The effects of rainfall were already important on day 3 of the integration over the anomaly area and on day 6 over parts of Scandinavia outside the anomaly area. The experiment was repeated with a version of the model in which the prevailing flow over Europe was less weak with increased moist westerly flow from the Atlantic. (16 refs.)

110583 Nonlinear mountain waves in two and three spatial dimensions. W.R.Peltier (Dept. of Phys., Univ. of Toronto, Toronto, Ontario, Canada), T.L.Clark.
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.527-48 (July 1983).
A three-dimensional, time-dependent, anelastic model is employed to simulate the evolution of nonlinear internal waves which are forced by stratified flow over isolated topography. Both two-dimensional and three-dimensional flows are considered. In the former case the discussion focuses upon the development of the wave field induced by a uniform mean flow with constant stability. The full three-dimensional model is employed to study the nonlinear development of atmospheric 'ship-waves' which have recently been observed in satellite photographs to the lee of oceanic islands in the Norwegian and Barents seas. The model is able to reproduce the characteristics of the observed wave patterns rather nicely when it is initialized with vertical profiles of wind and stability obtained through upper air ascents from stations located on the islands themselves. (17 refs.)

110584 A study of meteorological patterns associated with a lake confined by mountains—the Dead Sea case. M.Segal, Y.Mahrer, R.A.Pielke (Dept. of Atmospheric Sci., Colorado State Univ., Fort Collins, CO, USA).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.549-64 (July 1983).
A planned project to generate hydroelectric power by carrying Mediterranean water into the Dead Sea has stimulated a preliminary numerical model study of the regional meteorological patterns and the evaluation of some possible local climatic modifications. Predicted mesoscale meteorological patterns associated with two frequent synoptic conditions over the region are presented. Emphasis has been focused on illustrating and studying two general aspects of the thermal circulations generated by a lake which is confined between mountains (LMC): the effect of external flows on the LMC structure and the effects of lake water temperature on the LMC intensity. (33 refs.)

110585 Solutions to a model of a front forced by deformation. M.J.P.Cullen (Meteorological Office, Bracknell, England).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.565-73 (July 1983).
A semi-geostrophic deformation model of a front studied by B.J. Hoskins (1982) and F.P. Bretherton (1972) is studied further. It is shown that a unique solution of the Lagrangian conservation laws governing the motion can still be constructed after the front has formed. This solution shows that separate upper and lower fronts propagate into the fluid, and are separated by a region where only smooth variations occur. Finite difference solutions of the primitive equations are also given which converge to a front with the correct mean slope and maximum long-front velocity but without the correct variation in slope through the depth of the fluid. (5 refs.)

110586 A model of the feeder-seeder mechanism of orographic rain including stratification and wind-drift effects. D.J.Carruthers, T.W.Choularton (Phys. Dept., Univ. of Manchester Inst. of Sci. & Technol., Manchester, England).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.575-88 (July 1983).
Orographic enhancement of rain via the 'feeder-seeder' mechanism has been calculated using a stratified airflow model. The effect of wind drift on precipitation has been included. Comparisons have been made using potential flow models both in two and in three dimensions and in the model of M.J. Bader and W.T. Roach (1977). For high windspeeds ($\gtrsim 15$ m s^{-1}), when large enhancements occur, the potential flow treatment is sufficient. Inclusion of stratification does not significantly affect the total washout, although in the case of long hills (half-length ≥ 10 km) the precipitation maximum is moved upwind. For long hills the results are also in close agreement with the model of Bader and Roach. Over shorter hills both wind drift and non-hydrostatic effects are important. Wind drift decreases both maximum and total enhancements. (16 refs.)

110587 Laboratory studies of the charging of soft-hail during ice crystal interactions. E.R.Jayaratne, C.P.R.Saunders, J.Hallett (Phys. Dept., Univ. of Manchester Inst. of Sci. & Technol., Manchester, England).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.609-30 (July 1983).
A laboratory investigation of electric charge transfer during the impact of vapour-grown ice crystals and supercooled water droplets upon a simulated soft-hailstone target has shown that the magnitude of the charge transferred to the riming surface when crystals separate from it is a function of temperature, crystal dimension, relative velocity, liquid water content, and impurity content of the water droplets and hence the impurity content of the riming target. The sign of the charge transfer depends on temperature, liquid water content and droplet and rime impurity content. It is suggested that there are two distinct charge transfer processes during crystal interactions with an ice target, the dominant one requiring the presence of supercooled water droplets. Careful control and knowledge of the microphysical properties of the clouds used in these experimental simulations has permitted an examination of charge transfer under many of the conditions used in previous studies. (32 refs.)

110588 The scavenging of particles by electrified drops: radar echo intensification following lightning. E.Barker, J.A.Bicknell, R.F.Griffiths, J.Latham, T.S.Verma (Phys. Dept., Univ. of Manchester Inst. of Sci. & Technol., Manchester, England).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.631-44 (July 1983).
A series of laboratory experiments were performed in an effort to improve the understanding of the physics of the echo-intensification phenomenon, in which the radar reflectivity of a region of a thundercloud increases rapidly immediately following the occurrence of lightning within it. Measurements were made of the charges, q, deposited on falling water drops when they engage in direct interactions with positive corona streamers in a uniform electric field, E, just above the limit for propagation, E_0. As the drop radius increased from 12 to 950 μm, q increased from about 10^{-13} to about 10^{-10}C; and C increased as E was raised above E_0. The collection efficiencies of drops in the radius range 40 to 120 μm was determined. A simple analysis indicates that reported echo-intensification observations cannot be explained in terms of these enhanced collection efficiencies, but could possibly be a consequence of the greatly enhanced velocities (and hence growth rates) of drops of radius ~ 100 μm highly charged by direct interaction with corona streamers in the intense electric fields of a thundercloud. (27 refs.)

110589 Turbulent dispersion from an elevated line source: Markov chain simulations of concentration and flux profiles. B.J.Legg (CSIRO Div. of Environmental Mech., Canberra, Australia).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.645-60 (July 1983).
A Markov chain model that simulates the trajectories of fluid particles in turbulent flow is described. It incorporates fluctuations in vertical and streamwise velocity, and can be used with velocities that have a skewed probability distribution. The model is used to estimate the distribution of heat downwind from an elevated line source in the boundary layer above a rough surface, and the results are compared with those from a wind tunnel experiment. The simplest model, with fluctuations in vertical velocity only, underestimates the plume depth by 4% to 22% at various distances downwind, and underestimates the rise in the mean height of the plume by 1.5 mm in 25.5 mm. The inclusion of streamwise velocity fluctuations increases the vertical plume width by 6% and also improves the prediction of the mean height of the plume. (31 refs.)

110590 A laboratory experiment on momentum and heat transfer in the stratified surface layer. K.Fukui, M.Nakajima (Dept. of Chem. Engng., Himeji Inst. of Technol., Himeji, Japan), H.Ueda.
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.661-76 (July 1983).
Stratification effects on transport processes in the atmospheric surface layer or in the wall region are investigated by a laboratory experiment. A fully developed stratified condition was attained in turbulent flow between horizontal parallel plates kept at different temperatures. The experiment was performed both for stable and unstable conditions and provided conclusive data on stratification effects. A local gradient model is proposed, based on the concept that stratification effects may be evaluated at the same non-dimensional distance from the wall $z^{+}(\equiv z u_{w}^{*}/\nu_{w}$; u_{w}^{*}, ν_{w}, being friction velocity and kinematic viscosity, respectively, at the wall), the effects depending only on $\zeta(\equiv z/L$; L being the Monin-Obukhov length). A comparison of the shear functions with previous field and laboratory experiments shows excellent agreement. By use of this concept, the measured intensities of velocity and temperature fluctuations near the wall are also well correlated with ζ. (35 refs.)

110591 Measurement of the solar spectral irradiance at Tanashi, Tokyo. III. M.Habu, M.Suzuki, T.Nagasaka (Electrotech. Lab., Ibaraki, Japan).
Res. Electrotech. Lab. (Japan), no.830, p.1-175 (Jan. 1983). In Japanese.
For pt.II see ibid., no.812, p.1-152 (1981). Deals with the measurement of spectral irradiance on the horizontal plane produced by global solar radiation, that is, the combination of direct solar radiation and sky radiation. The instrument covers the spectral region of 295.1 nm to 1083.7 nm and measurements are made at 54 wavelengths which are more densely distributed in the shorter wavelength range than i the longer one, by comparing global solar radiation with radiation from a standard lamp of spectral irradiance calibrated at the ETL. The period of measurements is from December 1978 to February 1980, and measured data of 318 sets in total have been obtained. The data are classified according to four seasons, four grades of atmospheric

turbidity, and four groups of total cloud amount. The following relationships have been examined: relationship between correlated color temperature of solar radiation and solar altitude; relationship between chromaticity coordinates of solar radiation and the Planckian locus; and relationship between illuminance produced by global solar radiation and solar altitude. (14 refs.)

110592 The scintillations for weak atmospheric turbulence using a partially coherent source. Y.Baykal, M.A.Plonus, S.J.Wang (Dept. of Electrical Engng. & Computer Sci., Northwestern Univ., Evanston, IL, USA).
Radio Sci. (USA), vol.18, no.4, p.551-6 (July-Aug. 1983).
The scintillation index for weak atmospheric turbulence is formulated for a partially coherent source (in space and time). Results for two cases when the detector has a slow and a fast response time are obtained. The solutions correctly reduce to the known scintillation index in the limit of coherent and incoherent sources. Transmitter aperture averaging and frequency averaging effects are shown as special cases. The limitations of the source model used and the solution obtained for a fast detector are discussed. (16 refs.)

110593 Rays and modes in a nonuniform troposphere. A.V.Kukushkin, V.G.Sinitsin (Inst. of Radiophys. & Electronics, Acad. of Sci., Kharkov, Ukrainian SSR).
Radio Sci. (USA), vol.18, no.4, p.573-81 (July-Aug. 1983).
A version of the hybrid (ray mode) representation of wave fields has been suggested which is convenient with refractive index profiles corresponding to simultaneously existing surface and elevated ducts. The field at the reception point is represented as a sum of normal modes peculiar to an isolated surface duct and an assembly of rays reflected from the elevated layer. (14 refs.)

110594 Statistical properties of centimeter and millimeter wave fields above the sea surface. M.G.Balan, S.B.Bespechnyi, N.V.Gorbach, Yu.A.Pedenko, V.B.Razskazovskii (Inst. of Radiophys. & Electronics, Acad. of Sci., USSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.11, p.899-906 (Nov. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.11, p.1260-8 (Nov. 1982). [received: Sept. 1983]
Discusses the results of experimental studies of the statistical properties of a direct signal (in the 3.2-cm, 8-, 4-, and 2-mm bands) propagating over a rough sea surface at small grazing angles. The authors show that the distribution law for signal amplitude fluctuations over a short path (0.75 km) is neither a Rice nor Rayleigh distribution, which are more characteristic of long path lengths (16 km). They compare the experimental and calculated values of the diffuse scattering coefficient for various values of the Rayleigh parameter, and analyze data on the mutual spatial correlation of amplitude fluctuations, making it possible to recognize a significant anisotropy in the horizontal and vertical planes. (16 refs.)

110595 Planetary lightning: Earth, Jupiter, and Venus. M.A.Williams, E.P.Krider (Inst. of Atmospheric Phys., Univ. of Arizona, Tucson, AZ, USA), D.M.Hunten.
Rev. Geophys. & Space Phys. (USA), vol.21, no.4, p.892-902 (May 1983).
Terrestrial lightning is usually produced by convective clouds that contain supercooled water, ice, and precipitation. The available evidence suggests that interaction between riming ice particles and supercooled water, followed by a gravitational separation of charged precipitation elements, is the dominant mechanism for cloud electrification on Earth. These mechanisms probably operate on Jupiter in the H_2O cloud, and optical images of lightning and whistlers have been detected by Voyager 1. Optical searches for lightning on Venus have been inconclusive, but have set an upper limit to the planetary flashing rate of about 30 km^{-2} yr^{-1}. (108 refs.)

110596 Organic films on atmospheric aerosol particles, fog droplets, cloud droplets, raindrops, and snowflakes. P.S.Gill, T.E.Graedel (Bell Labs., Murray Hill, NJ, USA), C.J.Weschler.
Rev. Geophys. & Space Phys. (USA), vol.21, no.4, p.903-20 (May 1983).
Surface-active organic molecules are common constituents of atmospheric aerosol particles, raindrops, and snowflakes. The authors review the literature pertaining to organic films on aqueous surfaces, and the surface-active organic compounds in atmospheric water. New measurements of surface tension of aqueous solutions of common atmospheric organic compounds (β-pinene, *n*-hexanol, eugenol and anethole) are reported, and it is demonstrated that the compounds produce films with properties similar to those of the more well known surfactants. It is concluded that organic films are probably common on atmospheric aerosol particles and that they may occur under certain circumstances on fog droplets, cloud droplets, and snowflakes. (155 refs.)

110597 Organic material in the global troposphere. R.A.Duce (Center for Atmospheric Chem. Studies, Graduate School of Oceanography, Univ. of Rhode Island, Kingston, RI, USA), V.A.Mohnen, P.R.Zimmerman, D.Grosjean, W.Cautreels, R.Chatfield, R.Jaenicke, J.A.Ogren, E.D.Pellizzari, G.T.Wallace.
Rev. Geophys. & Space Phys. (USA), vol.21, no.4, p.921-52 (May 1983).
Reviews the information presently available on concentration distribution, sources, sinks, and atmospheric transformation reactions of organic matter in the global troposphere. The data base for tropospheric organic compounds is very small. However, it is apparent that while anthropogenic sources often dominate the atmospheric chemistry of organic material in urban and near-urban air, a key to understanding the global cycling of tropospheric organic substances is a clear understanding of the interaction of the atmosphere with the terrestrial and marine biosphere. (215 refs.)

110598 Chemical composition of precipitation. V. N.Kukubu, H.Saeki, A.Fujitsuka (Univ. of Electro-Communications, Tokyo, Japan).
Rep. Univ. Electro-Commun. (Japan), vol.33, no.2, p.247-56 (Feb. 1983).
For pt.IV see ibid., vol.32, no.1, p.49-57 (1981). The results of the determinations made from April 1979 to March 1980 around Tokyo are reported. Ten sampling stations were selected from Tokyo and Kanagawa Prefecture. The precipitations were recovered every month. The samples were filtered and rain and insoluble materials were separated as in preceding reports. Total amount of rain water, pH values, total amount of insoluble materials, redox potential, Na, K, Ca, Mg, F, Cl, and SO_4 are determined. The variations of chemical composition of precipitation and of the chemical constituents are discussed. Secular change of the chemical constituents is also described. (5 refs.)

110599 The current status of the knowledge of stratospheric ozone. H.Suzuki (Chem. Div., Daikin Kogyo Co., Osaka, Japan).
Refrigeration (Japan), vol.58, no.666, p.355-71 (April 1983). In Japanese.
Reviews the use of freon gas and its connection with the ozone problem. The author considers atmospheric structure and the characteristics of the ozone layer in the stratosphere. The emergence of theories related to the depletion of the ozone layer by chlorofluorocarbons (CFCs) is reconsidered and a comparison is made between predicted and observed changes. CFC sinks and photochemical reactions are discussed and presently observed changes in the ozone layer are analyzed and compared to the latest theories. Effects of ozone depletion on the flora and fauna are examined and global efforts to control CFC use are described. (10 refs.) *M.J.C.*

110600 Circumglobal transport of the El Chichon volcanic dust cloud. A.Robock, M.Matson (Dept. of Meteorology, Univ. of Maryland, College Park, MD, USA).
Science (USA), vol.221, no.4606, p.195-7 (8 July 1983).
The stratospheric dust cloud from the 4 April 1982 eruption of El Chichon volcano in southern Mexico was observed to travel completely around the world in a 3-week period. Images from satellites operated by the National Oceanic and Atmospheric Administration were used to prepare daily maps of the location of the volcatile dust cloud, which is the largest and longest-lasting one so far observed with satellite imagery. (2 refs.)

110601 Some properties of the radioactivity of radon and thoron daughters in certain meteorological conditions. O.Sima (Facultatea de Fizica, Univ. Bucuresti, Bucuresti, Rumania), C.Dovlete, M.Alexandrescu.
Stud. & Cercet. Fiz. (Rumania), vol.35, no.6, p.537-45 (1983). In Rumanian.
The radioactivity of Rn-222 and Rn-220 daughter products in aerosols was measured 12 times a day during two periods in autumn (September 1977) and winter (February 1978). The results are discussed in connection with several meteorological parameters. The strong influence of the snow layer thickness on the thoron flux from soil to atmosphere is demonstrated. The correlation of aerosol radioactivity with some factors that condition the turbulent diffusion in the boundary layer is also presented. (12 refs.)

110602 Experimental validation of a spectral direct solar radiation model. R.Guzzi, G.Lo Vecchio (Istituto di Fisica, Univ. di Ferrara, Ferrara, Italy), R.Rizzi, G.Scalabrin.
Sol. Energy (USA), vol.31, no.4, p.359-63 (1983).
A model of spectral direct radiation of the Sun at the ground compared with the spectral measurements performed by a monochromator has evidenced a satisfactory agreement. However, some discrepancies, mainly in the shorter wavelength range, have been evaluated. In order to point out the causes of these discrepancies a long series of data of direct integral radiation, water vapour content, aerosol turbidity together with standard meteorological data were measured. These causes are defined by means of a statistical analysis. (16 refs.)

110603 Contribution to the study of solar radiation in Burgos, Spain. A.de Miguel, J.Bilbao (Dept. Mecanica y Termologia, Colegio Univ. de Burgos, Burgos, Spain).
Sol. Energy (USA), vol.31, no.4, p.365-75 (1983).
A series of daily measurements of global solar radiation on horizontal surface realized during the period 1978-82 in Burgos, Spain, is analysed. The mean decadic values show fluctuations, in the spring and at the beginning of the summer especially. The absolute maximums generally appear in July with values that oscillate between 23 and 26 MJm^{-2}, and the minimums in January or December with values between 4 and 5 MJm^{-2}. Averaging the analogous months the authors obtain the maximum in July with a value of 23 MJm^{-2}. The authors have studied the elemental statistic characteristics and remark that the interquartile range is small in the winter months and increases in the spring and summer. The number of the days in which the radiation has remained inferior to a given value has been calculated in the frequency analysis, remarking that in the days corresponding to the period of the winter appear radiation values inferior to 10 MJm^{-2} and only 3% of July days are below this value. The authors have defined and determined the potential radiation and have calculated the extraterrestrial radiation in order to know the attenuation of global radiation in its passage through the atmosphere. The authors remark that the energy percentage transmitted by the atmosphere increases from winter to summer, a maximum value of 59% is obtained in July and a minimum of 30% in December. The atmospheric transparency without clouds oscillates between 71% in the spring and 62% in the winter. (8 refs.)

110604 An interpretation of the coefficients of the Angstrom equation. K.J.A.Revfeim (Meteorological Service, Wellington, New Zealand).
Sol. Energy (USA), vol.31, no.4, p.415-16 (1983).
In the report which suggested a linear relationship between global radiation and relative sunshine duration Angstrom simply referred to the coefficients as 'constants', with no physical interpretation being given. A physical model was developed by the author in 1981 to better utilize the information content of hourly sunshine fractions which is the common method of measuring suncard burns. This model has a simple interpretation, in terms of the mean and variance of sunshine fractions, which has the same form as the Angstrom equation. This model and its interpretation of the Angstrom equation is discussed. (8 refs.)

110605 Estimation of the total solar radiation from meteorological data in the Italian climatic area. O.A.Barra (Dept. of Phys., Univ. of Calabria, Cosenza, Italy).
Sol. Energy (USA), vol.31, no.4, p.427-8 (1983).
The Sabbagh-Sayigh-El Salam model [1977] developed for Saudi-Arabia has been properly modified in order to work in the Italian climatic area. The total solar radiation is evaluated by the model with a relative error never greater than 10 per cent, i.e. of the same order of magnitude as the errors affecting the available experimental data. The same model can probably be extended to the whole Mediterranean area or to other temperate climates with simple small variations of the numerical values of the model parameters. The model gives the total solar radiation for all the sites where meteorological data are available and it is absolutely reliable for solar system design purposes. (14 refs.)

110606 Mesoscale numerical weather forecasting. N.F.Vel'tishchev, A.A.Zhelnin, V.Z.Kisel'nikova, E.M.Pekelis, D.Ya.Pressman (Hydrometeorological Res. Center, USSR).
Sov. Meteorol. & Hydrol. (USA), no.4, p.1-9 (1982). Translation of: *Meteorol. & Gidrol. (USSR)*, no.4, p.5-15 (1982).
A model for the local forecasting of meteorological elements based on the equations of deep convection considering Coriolis force is described. (20 refs.)

110607 Spatial correlation functions of humidity in Western Siberia and northern Kazakhstan. L.P.Kuznetsova, T.A.Mozhina (Inst. of Water Problems, USSR).
Sov. Meteorol. & Hydrol. (USA), no.4, p.35-9 (1982). Translation of: *Meteorol. & Gidrol. (USSR)*, no.4, p.44-9 (1982).
Seasonal spatial correlation functions of humidity at the level of isobaric surfaces 850 and 700 mb and moisture content in the troposphere calculated from the mean monthly values of the indicated characteristics during the period 1961-1970 for Western Siberia and Northern Kazakhstan are examined. (6 refs.)

110608 Attenuation of signals in hydrometeors on satellite communication links. M.B.Kaplunov.
Telecommun. & Radio Eng. Part 1 (USA), vol.36, no.8, p.30-4 (Aug. 1982). Translation of: *Elektrosvyaz (USSR)*, vol.36, no.8, p.34-6 (Aug. 1982).
The attenuation of signals by hydrometeors (rain, snow, fog, etc.) is a substantial obstacle in the widespread use of frequencies above 10 GHz, assigned to satellite communications. A large volume of statistical data on signal atte-

nuations in satellite links has been gathered during recent years. This data enables the method described to be used to calculate the energy parameters of satellite communication lines as they apply to cases of practical importance, such as significantly large ranges between the stations and the time-division multiple access. The calculations are reduced to simple formulas and graphs. (5 refs.)

110609 A method for calculating the attenuation of radio waves in rain on ground links. E.A.Larin.
Telecommun. & Radio Eng. Part 1 (USA), vol.36, no.8, p.48-55 (Aug. 1982). Translation of: *Elektrosvyaz (USSR)*, vol.36, no.8, p.48-55 (Aug. 1982).
The possibility of constructing wideband communications systems, followed by the solution of the problem of their electromagnetic compatibility with other radio devices is the basic reason for the present investigations of the propagation of radio waves at frequencies above 10 GHz. The method for predicting the probable attenuation of radio signals in the rain was derived by processing a large volume of meteorological data. It was possible to detect the required variations of the spatial parameters of the rain as functions of its average parameters at the point of observation. (11 refs.)

110610 Increasing the accuracy of signal level computations on tropospheric radio links. O.N.Kiselev.
Telecommun. & Radio Eng. Part 1 (USA), vol.36, no.8, p.56-7 (Aug. 1982). Translation of: *Elektrosvyaz (USSR)*, vol.36, no.8, p.54 et seq. (Aug. 1982).
Outlines statistical methods for calculating mesoinhomogeneities in tropospheric radio links. (5 refs.)

110611 The gain in signal stability when using adaptive receiving antennas for long-distance tropospheric communications links. O.P.Frolov.
Telecommun. & Radio Eng. Part 1 (USA), vol.36, no.9, p.26-9 (Sept. 1982). Translation of: *Elektrosvyaz (USSR)*, vol.36, no.9, p.44-6 (Sept. 1982).
The low level of the received signal from LTP (long-distance tropospheric propagation) communication links results in the need to use receiving antennas with a large aperture area. In the situation under consideration, it is good practice to use reflector type antennas which 'pick up' an incident tropospheric wave and reflect it to the focal region. The positioning in the focal region of a special radiator with control elements which change the field distribution in the aperture of the radiator, provides a complex interface between the distribution of the external field and the inherent distribution of the adaptive radiator. (4 refs.)

110612 On the instability of internal Alfven-gravity waves in stratified shear flows. A.S.Narayanan (Dept. of Appl. Maths., Indian Inst. of Sci., Bangalore, India).
Z. Angew. Math. & Phys. (Switzerland), vol.34, no.4, p.545-9 (July 1983).
Internal Alfven-gravity waves and their stability characteristics for an inviscid, nondissipative, Boussinesq fluid undergoing shear in the presence of a lower rigid boundary is studied. The model consists of a layer of constant shear capped by a layer of constant velocity. The Brunt-Vaisala frequency is assumed to be uniform throughout the fluid. The unstable modes have wavelengths which are close to those of the internal Alfven-gravity waves which propagate from the troposphere into the ionosphere. (10 refs.)

110613 Wave propagation and remote sensing. D.T.Gjessing (Royal Norwegian Council for Sci. & Industrial Res., Kjeller, Norway).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.xvii-xxx
In general terms, an object probed by electromagnetic waves can be characterized by the distribution of scatterers along and transverse to the propagation direction, the chemical surface structure of the object, the surface temperature and the motion pattern. A unified set of first order expressions derived from basic physical principles characterizing the scattering object is presented. From these it is shown how the propagation medium affects the results of the various remote sensing techniques. In exactly the same way the factors which characterize the propagation medium in relation to communications are derived. It is shown that in regard to the influence of the propagation medium, the problems related to communications are very much unified with those of remote sensing. (10 refs.)

110614 Wave propagation in precipitation. P.DeLogne (Lab. de Telecommunications, Univ. Catholique de Louvain, Louvain-la-Neuve, Belgium).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.xxxi-xli
The emphasis of the paper is on fundamental concepts and on the development and justification of a unified theoretical model. The latter is applied to several topics and attention is drawn to some unsolved problems and potential research areas. (13 refs.)

110615 Analysis of multipath fading observations on certain microwave paths in British Columbia. N.Owen (British Columbia Telephone Co., Canada), E.Lee, M.Kharadly.
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.3-11
The paper gives the results of measurements carried out on twelve microwave links throughout the Province of British Columbia, Canada. The links are representative of those in three of the five main topographic-climatic regions of this large province. The salient features of the microwave links on the paths are given. The observations are given in terms of worst-month multipath fading probability as a function of fade depth, the number of fading events and the variation of monthly fading time over the measurement period. The diurnal fading characteristics of several paths are also shown. The analysis involves comparisons of certain parameters derived from the observations with those given in the literature and generalized in the CCIR formula. An attempt is made to explain the observations in terms of terrain and climate. (15 refs.)

110616 The PACEM experiment on line of sight multipath propagation. M.Sylvain, F.Baudin, C.Klapisz, J.Lavergnat, S.Mayrargue, J.P.Mon, B.Nutten, M.Rooryck (CNET, Issy-les-Moulineaux, France).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.13-23
This paper describes an experiment aimed at giving a physical insight into situations leading to multipath propagation (MP). The experiment ran over a two-month period on an overland 37 km path. It associated a wide band microwave link analyzer and measurements of temperature, humidity and wind from the ground up to 300 m. Furthermore acoustic sounders monitored the temperature structure of the lower atmosphere and a two frequency lidar gave humidity profiles. From the data, it is hoped (1) to point out the specific meteorological situations leading to MP, (2) to get a physical insight into the behaviour of the propagation medium under these conditions, and (3) to derive short term evolutive models for the temperature and humidity in the boundary layer. (34 refs.)

110617 Microwave multipath from sea reflections—the Bay of Fundy. A.R.Webster, W.I.Lam (Centre for Radio Sci., Univ. of Western Ontario, London, Ontario, Canada).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.25-30
The distribution in amplitude of direct and sea reflected rays on two separate microwave links across the Bay of Fundy are examined. Resultant fading statistics are also presented for the two data sets, which were obtained during different seasons, and these show significant differences. It is suggested that the root cause of much of the deep fading is the formation of atmospheric layers below the line of sight. (5 refs.)

110618 Rates of change of propagation medium transfer functions during selective fadings. L.Martin (CNET, Lannion, France).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.31-5
In France, on a 50 km path, propagation medium transfer functions have been recorded during multipath fadings. Some typical parameters of amplitude distortion curves, measured in the 11.25-11.65 GHz band, have been selected to characterize selective fadings. Rates of change of these parameters give information about variations of the selectivity phenomenon. The theoretical statistical laws which are best fitted to the experimental statistical distributions of these rates of change are log-normal. An attempt to relate the rates of change of one of these parameters to variations of tropospheric layers in the lower atmosphere is presented. (6 refs.)

110619 Effect of 'anomalous' tropospheric M-profiles over the sea on SHF field strengths. V.A.Kabanov, F.V.Kivva, V.A.Kortunov, V.G.Sinitsin, I.S.Tourgenev (Inst. of Radiophys. & Electronics, Acad. of Sci., Kharkov, Ukrainian SSR).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.47-8
The statistics of radio frequency field strengths (wavelengths $\lambda=30$ cm; 3 cm and 0.8 cm) and of vertical refractive index profiles were measured on several maritime paths of different lengths. The profiles were monitored with microwave refractometers both at the transmitter and receiver sites and at intermediate points of the path out at sea, in the latter case with the aid of airborne instruments. (2 refs.)

110620 Measurements of radio refractive index profiles at tropical and equatorial regions and their influence on line-of-sight microwaves links. N.R.Dhein (Centro de Estudos em Telecomunicacoes, Univ. Catolica, Rio de Janeiro, Brazil).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.49-55
This work deals with tropospheric propagation conditions in tropical and equatorial regions of Brazil, based on measurements of the vertical structure of lower atmosphere and microwave fading. The high probability of anomalous propagation phenomena has been a characteristic of line-of-sight microwave links in these regions. The fine structures of refractive index were obtained through the vertical displacement of refractometer along a tower and showed that tropospheric duct is the main cause of these fadings. A refractometer system furnished a continuous recording of the K-factor. Thus, it was possible to observe a large variation of this parameter along the day and to include this variation in the statistics. (7 refs.)

110621 Propagation anomalies in a 4, 7 and 11 GHz line of sight path. G.Roux, J.P.Mon (CNET, Issy-les-Moulineaux, France).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.57-68
An experiment aimed at giving some insight into the meteorological conditions leading to multipath propagation was conducted during two summer months in the south-west of France. The level of three carriers at 4, 7 and 11 GHz were recorded on a 48 km LOS path and simultaneously acoustic sounding monitoring of the lower atmosphere was performed at midpath together with temperature, humidity and pressure recording at four levels of an instrumented tower. Intense fading occurred almost every night. In this paper, a statistical study of the radioelectric and meteorological events observed is worked out and the analysis of a specific case is presented. (11 refs.)

110622 Statistics of radio refractivity and atmospheric attenuation in tropical climates. L.B.Kolawole (Dept. of Phys., Univ. of Ife, Ile-Ife, Nigeria).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.69-75
The statistics of radio refractivity and atmospheric absorption of centimetre and millimetre waves in the different climates of Africa are reported. Four main surface refractivity patterns are identified in line with the major climate regions of the continent. The seasonal variations of the surface refractivity are explained by a general consideration of the weather system across the continent. It is shown that the surface refractivity, N_s and ΔN, the refractivity decrease in the first kilometre height are well correlated over Africa and from this correlation the empirical relationship $\Delta N=-2.30 \exp(0.008630\, N_s)$ was deduced. (11 refs.)

110623 A comparison of radio-wave and in situ observations of tropospheric turbulence and wind velocity. M.H.A.J.Herben, W.Kohsiek (Dept of Electrical Engng., Eindhoven Univ. of Technol., Eindhoven, Netherlands).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.79-87
The importance of radio-wave scintillations introduced by tropospheric turbulence for both telecommunication and meteorological research is indicated. Amplitude, phase and phase-difference measurements of scintillation were performed at 30 GHz on an 8.2 km line-of-sight path. In-situ measurements of temperature and humidity fluctuations and wind velocity and direction were done about midway on the propagation path. The measuring systems are described, and theory is presented to derive the refractive-index structure parameter C_n^2 and wind velocity v from radio-wave scintillations and the in situ measurements. Formulas are given to scale C_n^2 and v with height. Finally, results of the experiments are presented and discussed. (21 refs.)

110624 Upper tropospheric structures observed with VHF radar at Arecibo. A.T.Waterman (Stanford Univ., Stanford, CA, USA), P.Czechowsky.
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.89-94
Data taken during December 1980 using a 50 MHz radar of the German SOUSY group and the large antenna at Arecibo are reported and analyzed. Data were taken at eight zenith angles and two azimuths (east and north).

Received power showed a rapid decrease in the lower 11 km, with a much slower decrease above, up to 20 km. Marked and persistent layers were present, the two strongest being at 14 km and 17 km. Measurements of echo power vs. zenith angle and estimates of Richardson's number indicated an atmospheric structure different from isotropic turbulence, thereby implying either a strong anisotropy or quasicoherent layers. Comparison of wind measurements with the radiosonde at San Juan showed good agreement in magnitude but less good agreement in direction. (15 refs.)

110625 Amplitude scintillation in propagation paths above 10 GHz. P.Basili, P.Ciotti, G.D'Auria, A.Silberman, D.Solimini (Istituto di Elettronica, Univ. di Roma, Rome, Italy), E.Matricciani.
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.95-101
After a theoretical introduction based on a spectral approach, experimental data taken on a 35 GHz line-of-sight radio link over the urban area of Rome, Italy, and on the 11 and 17 GHz earth-space path of the SIRIO propagation experiment are reported. Field amplitude distributions, covariance functions and spectral densities are reported for various meteorological conditions. Significant parameters of spectra of log-amplitude fluctuations, such as cut-off frequency and asymptotic values are discussed. For the SIRIO experiment, spectra of the sky brightness temperature fluctuations measured during the analyzed scintillation events are also reported. (7 refs.)

110626 An offsetting technique to study scintillations in direction of arrival in earth-space paths. E.Vilar, P.Lo, G.Weaver, H.Smith (Dept. of Electrical & Electronic Engng., Portsmouth Polytech., Portsmouth, England).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.103-10
This paper is concerned with the investigation of fluctuations in the direction of arrival in an earth-space path, and more specifically with the possibilities offered by the technique of offsetting a high gain antenna so that these fluctuations appear as fluctuations in amplitude superimposed on the usual amplitude scintillations. The paper introduces the method and the supporting preliminary theoretical background. This is followed by a description of the technique for the data analysis and remote sensing of the turbulent path. Results are presented and discussed together with theoretical and practical limitations. The receiving system is briefly explained. (12 refs.)

110627 Results obtained from attenuation measurements of the Deutsche Bundespost OTS-propagation experiment. F.Dintelmann (Forschungsinst. der Deutschen Bundespost, Darmstadt, Germany).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.113-17
Attenuation results obtained from radiometer and OTS-beacon measurements at 11.6 GHz are reviewed for a four-year period. Besides the average annual exceedance of attenuation and the worst-month statistics the diurnal variation of attenuation is investigated in particular. To this end an average day is defined and cumulative distributions of attenuation for eight consecutive three-hour periods are analysed. It is shown that during the afternoon and night hours the probability to exceed specified fade levels is much higher than for the average year but lower than for any month. Fade duration statistics are presented for a number of thresholds. For medium fade levels the distributions were found to be very similar. (8 refs.)

110628 First global results of the European Space Agency OTS propagation campaign. A.Laloux, M.Van Schingen, P.Sobieski (Lab. de Telecommunications, Univ. Catholique de Louvain, Louvain-la-Neuve, Belgium), G.Brussaard.
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.119-25
During the OTS propagation measurement campaign, the European Space Agency has collected an important database. This paper describes the first global results of the processing of this database. Radiometer calibration and analysis of attenuation and crosspolarisation for different frequencies and polarisations are discussed on a global statistical basis or using an event by event approach. (2 refs.)

110629 Experimental study of propagation characteristics in millimeter wave region. Y.Furuhama, T.Manabe, T.Ihara, K.Tohma, K.Kitamura, Y.Imai (Radio Res. Labs., Min. of Posts & Telecommunications, Tokyo, Japan).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.165-71
A propagation experiment at 50.4, 81.8, 140.7, and 245.5 GHz has been conducted on a horizontal path of 810 m since October 1982. Preliminary results of the experiment are introduced. In the case of heavy rainfall whose rate is greater than several 10 mm/h, there is no distinctive difference among the attenuations at 81.8, 140.7, and 245.5 GHz, and furthermore the attenuation at 245.5 GHz is slightly smaller than that at 140.7 GHz around the peak of rainfall. Attenuations due to fog and water vapor are also observed. The maximum variation due to fog at 245.5 GHz is about 1.8 dB and this, under the Rayleigh approximation, corresponds to the floating liquid water content of about 0.15 g/m^3. (8 refs.)

110630 Theoretical and experimental study of propagation attenuation for rain in equatorial and tropical areas. F.Moupfouma, J.Tiffon (CNET, Issy-les-Moulineaux, France).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.185-92 In French.
Rain attenuation prediction depends on the raindrop size spectrum of a given climatic region. Raindrop size distributions for the equatorial and tropical climates are presented. These were indirectly calculated from data collected during 16 months in the People's Republic of Congo. Predicted line of sight attenuation, derived from this distribution, is compared with experimental data collected in the Ivory Coast. Finally, various results of a 2 months experiment performed at 13 GHz in the Ivory Coast on a radio link in vertical and horizontal polarisations are presented. (17 refs.)

110631 Rain rate profile effects on radiowave attenuation above 10 GHz. Z.W.Zhang, H.J.Li, C.Q.Zhang (Wuhan Univ., Wuhan, China).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.193-6
Using the data from weather radar and considering the inhomogeneity of rain, a model of rain rate profile without depending on frequency was obtained. Total rain attenuation over earth-space path above 10 GHz can be calculated simply using this model. In this paper rain attenuation for frequencies of 12 GHz, 20 GHz, 30 GHz with elevations of 23°, 45°, 60° are obtained. The results both from calculation and from experiment made at The Radio Wave Propagation Laboratory of Wuhan University and other authors agree very well. It shows that this model of rain rate profile can be applied generally. (7 refs.)

110632 Statistics on the fine scale structure of rain in Stockholm 1977-79. L.Falk (Nat. Defence Res. Inst., Linkoping, Sweden).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.197-9
Data based on three years measurements of rain rates south of Stockholm 1977-79 with a network of 24 rain gauges have been used to investigate the fine scale structure of rain with particular regard to slant-path propagation. Statistics were calculated for annual, monthly and daily variations of rain rates and the spatial correlation was used to study the extension of rain cells as well as path averages connected with rain attenuation. (2 refs.)

110633 100 GHz open-resonator measurements of artificial precipitation and fog propagation parameters. D.J.Harris, S.Pickard (Univ. of Wales Inst. of Sci. & Technol., Cardiff, Wales).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.201-5
An open-resonator is used at 100 GHz to investigate the extinction properties of individual falling water drops and the attenuation of artificial advection fogs. The fog attenuation is also measured simultaneously at 0.63 μm wavelength. The measured extinction cross-section of water drops in the 2.8 to 5.8 mm diameter range are very close to the predictions using Mie theory and the Ray model for calculation of the complex refractive index at 100 Ghz. For a falling water drop with near-terminal velocity, the cross-section for horizontal polarisation is on average 5% greater than for vertical polarisation. Attenuations in fog range up to 10 dBm^{-1} at 0.63 μm and 40 dBkm^{-1} at 100 Ghz, the ratio of the two being approximately 500 for most conditions. This is greater than predictions using given particle size distributions for heavy fog, but recent observations which suggest a considerable sub-micron particle content could explain the discrepancy. (17 refs.)

110634 Prediction of rain attenuation based on point rain rate statistics for Alexandria, Egypt. H.N.Kheirallah (Dept. of Electrical Engng., Alexandria Univ., Alexandria, Egypt).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.219-24
Rain rate data collected over the period of 28 years in Alexandria is presented. Statistical distributions for the over-the-year and the worst-month data are shown and compared with distributions suggested by the CCIR for the region. Corresponding attenuation statistics on hypothetical terrestrial and earth-space links are then given indicating that rain attenuation should not be neglected when designing microwave links operating above 10 GHz in the vicinity of Alexandria. (9 refs.)

110635 Influence of raindrop oscillations on coherent forward scattering of microwaves in rain. M.Chandra, N.J.McEwan, P.A.Watson (Dept. of Electrical & Electronic Engng., Univ. of Bradford, Bradford, England).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.239-45
Using a previously proposed model for raindrop oscillations together with point matching scattering computations, the effective scattering amplitudes of oscillating raindrops for coherent forward scattering have been calculated. Results are also given for raindrops possessing modified axial ratios deduced from radar-distrometer measurements and for non-oscillating Pruppacher-Pitter oblate raindrops. The propagation parameters relating to the coherent field of microwaves propagating through rain are given for 11.575 GHz and 20.0 GHZ. The results for the three rain models are compared between themselves and with an empirical A/XPD relation. (14 refs.)

110636 Capability of surface-based clear-air Doppler radar for monitoring meteorological properties in elevated layers. E.E.Gossard (NOAA, Univ. of Colorado, Boulder, CO, USA), R.B.Chadwick, T.Detman, J.Gaynor.
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.413-24
Radars and acoustic sounding systems sense properties of the turbulence structure of the atmosphere. If atmospheric turbulence can be related to the mean gradient parameters, radars and acoustic sounders can provide information about height profiles of quantities such as temperature and refractive index as well as wind. In this paper turbulent and mean quantities were measured on the 300-m meteorological tower at Erie, Colorado, USA, and the relationships between the turbulent and mean gradient quantities were examined in order to evaluate hypotheses for simplifying the kinetic energy balance and refractive index variance equations. FM-CW radar measurements of Doppler spectral width were also made for comparison with tower-measured velocity spectra. Height distributions of ϵ within stable layers are shown and viscous cutoff radar wavelengths calculated. (6 refs.)

110637 Radar modeling of space diversity associated with slant path rain attenuation at variable path angles, frequencies, and drop size distributions. J.Goldhirsh (Appl. Phys. Lab., Johns Hopkins Univ., Laurel, MD, USA).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.437-45
Single and joint terminal slant path attenuation statistics at frequencies of 28.56 and 19.04 GHz have been derived employing a radar data base obtained over a three year period at Wallops Island, Virginia. Statistics were independently obtained for path angles of 20°, 45°, and 90° for purposes of examining how path angle influences both single terminal and joint probability distributions. A prediction technique is demonstrated to work well for calculating both single and joint terminal distributions at other path angles. Both diversity gains and autocorrelation function dependence on site spacing were determined employing the radar modeling results. Comparisons with other investigators are presented. (11 refs.)

110638 Attenuation of radio waves by atmospheric wet ice and mixed phase hydrometeors. Y.M.M.Antar, A.Hendry (Div. of Electrical Engng., Nat. Res. Council of Canada, Ottawa, Ontario, Canada).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.455-61
Observations of radio wave attenuation by wet ice and mixed phase hydrometeors along a propagation path are reported. Included are further studies on attenuation by snow flakes in the melting region during stratiform precipitation, attenuation by wet snow flakes during a snow storm, and attenuation by hail on an Earth-space path. Polarization diversity radar measurements at 16.5 GHz along with some satellite beacon attenuation measurements at 28.56 GHz are presented. Only situations in which rain effects along the path were small are considered. (14 refs.)

110639 Assessment of the intrinsic rain profile parameters from radar and raingauge data. C.Capsoni, G.Macchiarella, M.Mauri, A.Paraboni (Politecnico di Milano, Milano, Italy).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.463-8
This paper presents some statistics of the intrinsic rain profile parameters obtained from meteorological radar and from raingauge data. These parameters are merely meteorological but encompass the whole profile related information needed for evaluating path-integrated parameters such as link attenuation, anisotropy etc. Areas to which these results apply are: attenuation prediction methods, short-term frequency scaling, modelling of rain structures and others. The single and bidimensional statistics here presented are all of conditioned type in order to link them to some variable (such as point rain-intensity or attenuation) the long-term statistic of which is well known for the locality of interest. (12 refs.)

110640 Effect of large-scale anisotropic refractive index inhomogeneities on the strength of the coherent VHF signal component beyond the horizon. A.V.Kukushkin, V.D.Freulicher, I.M.Fuchs (Inst. of Radiophys. & Electronics, Acad. of Sci., Kharkov, Ukrainian SSR).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.487-93
The propagation of microwaves through a non-uniform troposphere with anisotropic random inhomogeneities of the refractive index, characterized by horizontal scale lengths of several hundred meters, is shown to be reducible to the problem of wave propagation through a random stratified medium. The effect of this random stratification upon the field in the 'near trans-horizon' region, i.e. 100 to 200 km from the transmitter, is estimated. The expressions for the field moments obtained in the paper allow explaining the greater fading depths which acompanied a growth in the coherent component in some experiments. The average intensity of the signal grows with the RMS fluctuations in the refractive index, even if the average gradient thereof is too small for producing enhanced refraction. (11 refs.)

92.60S Climatology

110641 A general circulation model study of January climate anomaly patterns associated with interannual variation of equatorial Pacific sea surface temperatures. M.L.Blackmon (Nat. Center for Atmospheric Res., Boulder, CO, USA), J.E.Geisler, E.J.Pitcher.
J. Atmos. Sci. (USA), vol.40, no.6, p.1410-25 (June 1983).
A general circulation model has been run in the perpetual January mode to produce several long-term simulations, each distinguished by a different imposed equatorial Pacific sea surface temperature. From each of these simulations the authors have extracted an eight-member ensemble of 90-day averaged fields. Ensemble-mean difference maps are presented. These results are compared with observational studies in the literature that present difference maps of Northern Hemisphere winter fields composited according to some index related to the two extremes of equatorial Pacific sea-surface temperature variation. The results show many anomaly patterns of high statistical significance that are also in good agreement with those observed. In the tropics, these include 990 mb wind, sea level pressure and rainfall anomalies constituting the Southern Oscillation, as well as a 200 mb height anomaly at all longitudes. (26 refs.)

110642 The influence of poloidal motions and latent heat release on the equilibrium ice extent in a simple climate model. B.Saltzman (Dept. of Geology & Geophys., Yale Univ., New Haven, CT, USA), A.D.Vernekar.
J. Atmos. Sci. (USA), vol.40, no.6, p.1426-34 (June 1983).
A zonal-average, annual-mean, statistical-dynamical climate model governing two domains (the atmosphere and a subsurface medium consisting of either ice or 'swamp'), and including the dynamics of mean poloidal motions and the hydrologic cycle as well as the ice-albedo feedback, is integrated numerically as a function of the solar constant. The adiabatic effect of the mean poloidal motion is to cool the system in the region of the ascending branch of the Ferrel cell (thereby promoting an advance of the equilibrium ice extent in this region) and to warm the system in the region of the descending branch (hence posing a 'barrier' to the ice advance in this region). This latter barrier effect is amplified as the solar constant is reduced because the subtropical descending motion increases in magnitude as the ice advances. (24 refs.)

110643 Climatic information over the last century deduced from a detailed isotopic record in the south pole snow. J.Jouzel, L.Merlivat (Lab. de Geochimie Isotopique, CENS, Gif-sur-Yvette, France), J.R.Petit, C.Lorius.
J. Geophys. Res. (USA), vol.88, no.C4, p.2693-703 (20 March 1983). [received: Sept. 1983]
A continuous and very detailed deuterium profile was obtained from the analysis of about 900 firn samples from the south pole representing the snow accumulated over the last 100 years. Seasonal variations are well preserved in the firn, allowing the samples to be dated back to 1887 with an accuracy probably better than 5 years. Snow accumulation rates are calculated. From a thorough examination of data relative to the very well documented 1957-78 period, mean annual and maximum deuterium values and annual deuterium amplitude are shown to be correlated with the corresponding mean annual and summer temperatures and the annual temperature amplitude. Winter temperature and deuterium minima are poorly correlated, which is attributable to the large temperature inversion during winter. As a whole, this work is very encouraging for the use of stable isotopes as a tool for past temperature reconstruction over periods for which only weak variation are expected. (48 refs.)

110644 140000-yr isotope climatic record from raised coral reefs in New Guinea. P.Aharon (Dept. of Geology, Louisiana State Univ., Baton Rouge, LA, USA).
Nature (GB), vol.304, no.5928, p.720-3 (25 Aug. 1983).
Reports the results of an oxygen isotope abundance study of the giant clam Tridacna gigas from a sequence of uplifted coral reefs in New Guinea which provides a detailed record of changes over the past 10^5 yr in the surface ocean isotope chemistry and temperature. The combined utilization of sea level and $^{18}O/^{16}O$ data allows a quantitative evaluation of ice volume and temperature factors. The results also contribute to resolving the question as to the exact time-relationship between temperature change at low latitudes and ice accumulation at the latitudes of the glacial ice caps. (36 refs.)

110645 Evidence from north-west Canada for an early Holocene Milankovitch thermal maximum. J.C.Ritchie (Scarborough Coll., Univ. of Toronto, Scarborough, Ontario, Canada), L.C.Cwynar, R.W.Spear.
Nature (GB), vol.305, no.5930, p.126-8 (8 Sept. 1983).
According to the Milankovitch theory of global climatic change, maximum summer solar radiation at high latitudes of the northern hemisphere occurred at 10000 yr BP. In particular, it predicts summer solstice radiation greater by 9-10%. This article summarizes pollen record data from sites in the northwest corner of Canada that directly support the Milankovitch hypothesis of climate change. (22 refs.)

110646 The geologic record of climatic change. T.J.Crowley (Dept. of Phys., Univ. of Missouri, St. Louis, MO, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.4, p.828-77 (May 1983).
Reviews the principal results from paleoclimate studies. A secular change in global insolation receipt is due to a 20-30% increase in solar luminosity since the formation of the Earth. On time scales of 10^6-10^8 years, paleogeographic factors (e.g. continental drift and sea level changes) have contributed significantly to temperature changes associated with transitions between nonglacial and glacial states. The origin of polar ice caps may result from ocean circulation changes that were caused by plate tectonic processes. Fluctuations of ice volume on a time scale of 10^3-10^5 years correlate with insolation variations caused by orbital perturbations. (440 refs.)

92.65 ATMOSPHERIC OPTICS

(see also 42.00 Optics)

110647 Extinction and liquid water content of fog at visible wavelengths. S.G.Jennings (Phys. Dept., Univ. Coll., Galway, Ireland).
Appl. Opt. (USA), vol.22, no.17, p.2514-15 (1983).
Recently, A.P. Lenham and M.R. Clay (see ibid., vol.21, p.4191, 1982) obtained high correlation for a linear relationship between a measured extinction coefficient in fog at wavelength $\lambda = 0.53$ μm and liquid water content. The liquid water content values were derived from number-size distribution histograms, which in turn were inferrred from transmission measurements at several wavelengths using an inversion algorithm. They also found that a high correlation between the infrared number concentration in the largest size category (6.4-12.8 μm radius) and the extinction coefficient. The purpose of the present author is to point out that high correlation between visible extinction and liquid water content for fog cannot be expected to hold in general. In addition, the correlation of number concentration with extinction is examined, and the conclusion is drawn that it is very unlikely in general for extinction to be linearly related to number concentration for fog size distributions at visible wavelengths. (8 refs.)

110648 Speckle statistics of atmospherically backscattered laser light. J.H.Churnside, H.T.Yura (Electronics Res. Lab., Aerospace Corp., Los Angeles, CA, USA).
Appl. Opt. (USA), vol.22, no.17, p.2559-65 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
The speckle pattern produced in laser light that has been backscattered by atmospheric aerosols is considered. The spatiotemporal correlation properties both of the optical field amplitudes and of the optical intensities are described. Analytical expressions are presented for the special cases of illumination by a short Gaussian pulse and by a CW source. (20 refs.)

110649 Comparison of calculated and measured spectral radiances of the atmosphere towards the zenith. M.Weller, U.Leiterer (Meteorologischer Dienst, Lindenberg, Germany).
Z. Meteorol. (Germany), vol.33, no.3, p.156-61 (1983). In German.
Compares calculated and measured spectral radiances of the atmosphere toward the zenith at 3200 m above the ground. Using the Schwarzschild-Eddington radiative transfer code its accuracy is in acceptable agreement with the accuracy of radiances and model input data which have been measured with a spectral photometer BAS. (9 refs.)

110650 Atmospheric infrared emission observed at altitude of 27000 to 28000 m. H.Sakai (Dept. of Phys. & Astron., Univ. of Massachusetts, Amherst, MA, USA), G.Vanasse.
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.366, p.165-72 (1983). (Modern Utilization of Infrared Technology VIII, San Diego, CA, USA, 26-27 Aug. 1982).
The molecules in the lower part of atmosphere are in thermal equilibrium with the local surrounding. The infrared emission resulting from their thermal excitation can be studied to determine their temperature and concentration profile in the atmosphere. The authors used a cryogenically cooled Fourier spectrometer mounted on a balloon-borne platform to study the infrared emission spectrum of atmosphere for this purpose. The experiment, which took place on October 7, 1981, at Holloman AFB, produced the analyzable data for more than two hours at altitude of 27000∼28000 m along the horizontal and the vertical line of sight. The spectral data extended from 550 cm^{-1} to 1000 cm^{-1} covering the CO_2 15 μ bands ($\Delta\nu_2=1$) with a resolution of 0.2 cm^{-1}. The data were found interesting on two accounts: (1) a continuum background feature was superimposed with the molecular emission feature; (2) the radiance level of the CO_2 15 μ bands observed along the horizontal line of sight varied by a much greater degree than expected. (8 refs.)

110651 Polarization structure of backscattering by water droplet and crystal clouds. V.E.Zuev, G.M.Krekov, M.M.Krekova.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.6, p.595-602 (June 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
The numerical solution of the nonstationary transfer equation in a vector form for the medium with anisotropic scattering centres has been obtained using the Monte-Carlo technique, using the scattering matrices measured experimentally. The numerical experiment has been carried out on polarization sounding of clouds with complex phase composition. The qualitative peculiarities of forming the backscattering signal from composed and crystal clouds are indicated which creates a physical basis for developing remote diagnostics methods. (12 refs.)

110652 On the problem of light scattering by horizontally inhomogeneous cloud. G.V.Mironova.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.6, p.603-12 (June 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
The problem of light propagation through the turbid medium layer modeling horizontally inhomogeneous cloud is solved in the small angle approximation by the perturbation method. The scattering coefficient variations are assumed to have the form of truncated Fourier series with the scattering phase function and the absorption coefficient being constant within the layer. The contribution of single scattering and multiple scattering into the total intensity of scattered light at various scattering angles and various thickness of the inhomogeneous layer is evaluated. The transformation of the horizontal distribution of the scattered light intensity is found to be dependent upon the layer level. (8 refs.)

110653 On a technique for operative correction for the transmission function in solving the problem of thermal sounding of the atmosphere. O.M.Pokrovskii, A.I.Belyavskii.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.6, p.613-21 (June 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
A modification of the technique for solution of the inverse problem in respect to the absorption characteristic of the atmosphere in the CO_2 15-μm band is discussed. The solution of the inverse problem is compared with the results of calculation of transmission fluctuations caused by variations in the profiles of water vapour, ozone, and aerosol in the troposphere and stratosphere. A scheme is discussed for latitudinal and zonal adjustment of an optical model for the solution of the thermal sounding problem using the data on peculiarities of the spatial-temporal structure of water vapour and ozone fields' fluctuations. (10 refs.)

110654 Comparison of radiative fluxes and flux divergences computed using different transmission functions under clear sky. T.I.Vassil'eva, M.G.Evseeva, E.L.Podolskaya.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.6, p.622-30 (June 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
New approximations of several integral transmission functions are proposed. Radiative fluxes, heating and cooling at various heights and latitudes in the cloudless atmosphere computed with different transmission functions or emissivities are presented. Comparison of results reveals that absorption of solar radiation in the near infrared is calculated correctly enough. Differences in computed longwave fluxes and coolings amount to 100% and more. The analytical approximation being of great importance, it must precisely describe both the transmission function and its derivative. (16 refs.)

110655 On meteorological parameter restoration from intraatmospheric measurements of optical refraction of cosmic sources. K.P.Gaikovich, A.S.Gurvich, A.P.Naumov.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.7, p.675-82 (July 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
Discusses the restoration of the refractive index and meteorological parameters profiles using intraatmospheric measurements of optical refraction of extraterrestrial sources. It is shown that if an observer is inside the atmosphere, the inverse problem is well specified with negative elevation angles and mathematically incorrect with positive ones. By the computer modelling, a possibility is investigated for the restoration of vertical profiles of temperature and pressure and estimates are given of the solution errors in the corresponding inverse problem. (14 refs.)

110656 Infrared absorption by rural organic aerosol. L.B.Galkina, Yu.S.Lyubovtseva, M.V.Shishkina, L.G.Yaskovich.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.7, p.683-95 (July 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
Using data from complex optical and mass spectrometric analyses of aerosol samples gathered in a purely rural (mountain) region near Abastumani, an evaluation is made of the contribution of organic submicron particles to aerosol absorption within the wavelength range $\lambda=2.5\text{-}12$ μm. The maximal absorption by the organic components is shown to be near $\lambda=3.4$ μm ($\alpha_{org}=8.0\times10^{-4}$ km^{-1}) and $\lambda=5.8$ μm($\alpha_{org}=3.3\times10^{-4}$ km^{-1}). A comparison is made of the contributions into absorption of different chemical constituents within a wide wavelength interval. (22 refs.)

110657 Infrared spectral radiance of the sky. A.Ben-Shalom, A.D.Devir, S.G.Lipson (Dept. of Phys., Technion-Israel Inst. of Technol., Haifa, Israel).
Opt. Eng. (USA), vol.22, no.4, p.460-3 (July-Aug. 1983).
A method of calculating the self-radiance of the sky based on the LOWTRAN-4 computer code is described. The method is a significant improvement on that included as an option in LOWTRAN-4 itself as a result of two modifications: a) The authors' method, unlike the one included in LOWTRAN-4, takes into account the radiance scattered into the line of sight. b) The model of the atmosphere in the computer code must be divided into a certain number of layers, each one having approximately uniform conditions. The authors' method uses a correct optimal division. Consequently, the method gives a better agreement with the experimental data, especially for long optical paths in the lower layers of the atmosphere. (7 refs.)

110658 Analysis of Mount St. Helens ash from optical photoelectric photometry. J.A.Cardelli (Dept. of Astron., Univ. of Washington, Seattle, WA, USA), T.P.Ackerman.
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.451-6 (July 1983).
Presents data from optical photoelectric observations of standard stars taken 48 hours after the 1980 July 23 eruption of Mount St. Helens which yield optical properties of the suspended dust particles. The analysis of the data centers of the use of Mie theory for determining the mean particle size and the column density of the particles in the absorbing layer. (12 refs.)

110659 Propagation of narrow light beams in rain. A.G.Rogachevskii (Inst. of Atmospheric Optics, Acad. of Sci., USSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.12, p.1025-9 (Dec. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.12, p.1449-54 (Dec. 1982). [received: Sept. 1983]
The intensity of a narrow light beam in rain is analyzed within the framework of a Markov approximation. The intensity is investigated as a function of the optical depth and a parameter which is a quantitative criterion of the narrowness of the beam. Estimates of the limits of applicability of the single-scattering approximation and of the Bouguer law are obtained. The possibility of efficient intensity focusing in rain is demonstrated. 93.55 INTERNATIONAL ORGANIZATIONS, NATIONAL AND INTERNATIONAL PROGRAMS

110660 The International Satellite Cloud Climatology Project (ISCCP): The first project of the World Climate Research Programme. R.A.Schiffer (WCRP, WMO Secretariat, Geneva, Switzerland), W.B.Rossow.
Bull. Am. Meteorol. Soc. (USA), vol.64, no.7, p.779-84 (July 1983).
The ISCCP was approved as the first project of the World Climate Research Programme and began its operational phase in July 1983. Its basic objective is to collect and analyze satellite radiance data to infer the global distribution of cloud radiative properties in order to improve the modeling of cloud effects on climate. (10 refs.)

93.65 DATA ACQUISITION AND STORAGE

110661 The estimation and removal of a linear drift from stacked data. P.L.McFadden, S.C.Constable (Res. School of Earth Sci., Australian Nat. Univ., Canberra, ACT, Australia).
J. Geophys. (Germany), vol.53, no.1, p.52-8 (1983).
In exploration systems with digital data acquisition the process of stacking is frequently performed to reduce the requirement for memory space. If the observations are corrupted by a drift then this drift is not averaged out by the stacking process. A robust method for least squares linear estimation and removal of the drift is presented together with an analysis of the errors involved. Examples with both synthetic and field data are presented to show the improvement in accuracy of signal recovery achieved by drift removal. (no refs.)

VLF signal recognition by cross-spectral analysis .... See Entry 110686

93.85 INSTRUMENTATION AND TECHNIQUES FOR GEOPHYSICAL RESEARCH

110662 Measurement of minor constituents in the middle atmosphere from IR limb emission spectra: a feasibility study. H.Oelhaf, H.Fischer (Meteorological Inst., Univ. of Munich, Munich, Germany).
Appl. Opt. (USA), vol.22, no.17, p.2515-18 (1983).
The feasibility of detecting fifteen trace constituents (O_3, CO_2, H_2O, CH_4, CO, N_2O, NO, NO_2, HNO_3, F-11, F-12, NH_3, SO_2, HF and HCl) against atmospheric background has been studied from IR limb emission spectra (4-100 μm) at various tangent heights in the middle atmosphere. The main properties of the mid- and/or far-IR bands of the molecule under investigation are compared, and specific problems (e.g. sparseness of atmospheric measurement, lack of line data, line wing shape) are indicated. The results of the investigations are discussed separately for each band or portion of a band. The calculations are mainly presented as graphs generally consisting of three types of figure for each species: (1) so-called S^*m spectra; (2) emission spectra for the two spectral resolutions of 0.1 and 1 cm^{-1}; (3) radiance profiles for selected spectral features corresponding to the 1-cm^{-1} resolution. (8 refs.)

110663 Remote sensing of stratospheric and mesospheric winds by gas correlation electrooptic phase-modulation spectroscopy. D.J.McCleese, J.S.Margolis (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
Appl. Opt. (USA), vol.22, no.17, p.2528-34 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
A method is described for directly measuring atmospheric winds in the 20-120 km altitude interval from a spacecraft. The principle of operation of the wind sensor is the measurement of the Doppler shift between the spectral absorption lines of a gas in a cell within the instrument and the thermal emission lines of the same gas in the atmosphere. The wind measurements are to be made with a spacecraft-borne gas correlation spectrometer viewing the limb of the atmosphere. The measurement of the wind-induced Doppler shift between the two spectra, and thence the magnitude of the wind itself, is accomplished by phase modulating the incoming thermal radiation (equivalent to frequency modulation) by means of an electrooptically active crystal to determine the frequency shift required to reestablish exact correlation between the lines in the cell and the lines from the atmosphere. Results of numerical simulations of the wind-sensor performance are presented showing the noise-equivalent-wind to be between 1 and 5 m/sec over most of the stratosphere and mesosphere. (17 refs.)

110664 Passive and active remote sensing of atmospheric precipitation. Y.Q.Jin, J.A.Kong (Dept. of Electrical Engng. & Computer Sci., MIT, Cambridge, MA, USA).
Appl. Opt. (USA), vol.22, no.17, p.2535-45 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
Both passive and active remote sensing of atmospheric precipitation are studied with the vector radiative transfer equations by making use of the Mie scattering phase functions and incorporating the raindrop-size distributions. For passive remote sensing the authors employ the Gaussian quadrature method to solve for the brightness temperatures. For active remote sensing an iterative approach carrying out to the second order in albedo is used to calculate for the bistatic scattering coefficients, the backscattering cross sections/unit volume, and the interchannel cross talks. The calculated results are plotted as a function of rainfall rates and compared to various available experimental data. The theoretical model is easily applied to the remote sensing of aerosol particles, smoke, fog, and haze at infrared and visible frequencies. (11 refs.)

110665 PRESTO: a programmable etalon spectrometer for twilight observations. W.A.Gault, R.H.Weins, G.J.Gotshalks, R.A.Koehler, G.G.Shepherd (York Univ., Toronto, Ontario, Canada).
Appl. Opt. (USA), vol.22, no.17, p.2551-5 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
A Fabry-Perot spectrometer specifically designed for measuring airglow intensities in twilight has been built using a feedback-controlled etalon from Queensgate Instruments, London. A single etalon passband (FWHM = 0.015 nm at 558 nm) is isolated by a narrowband (0.2-nm) interference filter. The passband of the etalon can be shifted in a random fashion by a digital command to a controlling circuit. Observing time is, therefore, used efficiently because only wavelengths of interest need be observed. Responsivity of the system is 1.3 counts $\sec^{-1}$ R^{-1} at 558 nm. The optics are contained in an outdoor climate-controlled enclosure connected by cables to a microcomputer at the indoor observing station. The computer controls all functions of the instrument and is capable of running long complex observing routines unattended using parameters specified by the observer. These parameters include meridian angles, filters (up to eight), integration times, and etalon steps. Some examples of twilight measurements are given. (9 refs.)

110666 Inverse methods for remote determination of properties of optically thick atmospheres. N.J.McCormick (Dept. of Nuclear Engng., Univ. of Washington, Seattle, WA, USA).
Appl. Opt. (USA), vol.22, no.17, p.2556-8 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
Methods of using CW and pulsed electromagnetic sources are compared for determination of the coefficients of the Legendre polynomial expansion of the single-scattering phase function from measurements of the multiply scattered radiance emerging from the surfaces of the atmosphere. Quadrature formulas are presented with which to calculate the angular moments of the radiance needed for the methods. (5 refs.)

110667 Evaporation derived from optical and radio-wave scintillation. W.Kohsiek (Royal Netherlands Meteorological Inst., De Bilt, Netherlands), M.H.A.J.Herben.
Appl. Opt. (USA), vol.22, no.17, p.2566-70 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
The determination of the evaporation from scintillation measurements at several wavelengths is discussed. The refractive-index structure parameter C_n^2 derived from the observed amplitude scintillation on a 30-GHz radio link is compared to a spot measurement of this quantity at a much lower height than that of the radio link. After free convection height scaling, a difference of a factor of 3 is found. This factor is discussed. A calculation of the evaporation from the observed radio-wave scintillation yields good agreement with calculations based on the Priestley-Taylor formula. (20 refs.)

110668 Multicolor laser altimeter for barometric measurements over the ocean: theoretical. C.S.Gardner, B.M.Tsai, K.E.Im (Dept. of Electrical Engng., Univ. of Illinois, Urbana, IL, USA).
Appl. Opt. (USA), vol.22, no.17, p.2571-7 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
The optical path length from a satellite to the Earth's surface is strongly dependent on the atmospheric pressure along the propagation path. Surface pressure can be measured by using a two-color laser altimeter to observe the change with wavelength in the optical path length from a satellite to the ocean surface. The statistical characteristics of the ocean-reflected pulses and the expected measurement accuracy are evaluated in terms of the altimeter parameters. The results indicate that a pressure accuracy of a few millibars is feasible. (9 refs.)

110669 Multicolor laser altimeter for barometric measurements over the ocean: experimental. J.B.Abshire, J.E.Kalshoven,Jr. (NASA Goddard Space Flight Center, Greenbelt, MD, USA).
Appl. Opt. (USA), vol.22, no.17, p.2578-85 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
Measurement theory and results from testing a breadboard multiwavelength (355-, 532- and 1064-nm) laser altimeter over horizontal paths are presented. They show that pressure accuracies of 3 mbar can be achieved when ranging at nadir to cube corner targets when using a 500-psec resolution waveform digitizer and utilizing new calibration techniques. Streak camera-based receivers will be required for the same or higher accuracies when ranging to the ocean surface. System design calculations for aircraft and spaceborne experiments are presented. (16 refs.)

110670 New technological developments for the remote detection of atmospheric hydroxyl radicals. I.S.McDermid, J.G.Laudenslager, T.J.Pacala (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
Appl. Opt. (USA), vol.22, no.17, p.2586-91 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
New developments in the areas of narrowband tunable excimer lasers, high-resolution high-rejection optical filters, and wavelength measurement devices are considered for application to the remote sensing of atmospheric hydroxyl radicals. The conclusion is that an increase in the SNR of 10^4 could readily be gained through the use of these new devices. Also, considerable reductions in size and electrical energy consumption could be realized. (28 refs.)

110671 Frequency-doubled CO_2 lidar measurement and diode laser spectroscopy of atmospheric CO_2. J.L.Bufton, T.Itabe (Instrument Electro-Optics Branch, NASA Goddard Space Flight Center, Greenbelt, MD, USA), L.L.Strow, C.L.Korb, B.M.Gentry, C.Y.Weng.
Appl. Opt. (USA), vol.22, no.17, p.2592-602 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
A lidar instrument based on pulsed frequency-doubled carbon-dioxide lasers has been used at 4.88 μm for remote sensing of atmospheric carbon dioxide. A tunable-diode laser spectrometer provided the high-resolution spectroscopic data on carbon-dioxide line strength and line broadening needed for an accurate differential absorption measurement. Initial field measurements are presented, and instrument improvements necessary for accurate carbon dioxide measurement are discussed. (30 refs.)

110672 Airborne measurements of laser backscatter from the ocean surface. J.L.Bufton (NASA Goddard Space Flight Center, Greenbelt, MD, USA), F.E.Hoge, R.N.Swift.
Appl. Opt. (USA), vol.22, no.17, p.2603-18 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
Laser backscatter data for the ocean surface near nadir have been acquired from an airborne lidar platform. The unique capability of this lidar instrument to scan both transmitted laser beam and receiver field of view up to 15° off nadir have made these data sets possible. Backscatter data were collected on eight separate missions using laser wavelengths at 337 and 532 nm and 9.5 μm. Statistics of the mean, standard deviation, and probability density function of backscatter were computed and analyzed in terms of prior analytical work that relates backscatter to wind speed and mean-square wave-slope statistics. The authors found the full width at half-maximum of the Gaussian-shaped mean backscatter pattern to range from 11 to 24° and the normalized standard deviation at a nadir-viewing angle to range from 0.1 to 0.6. They calibrated mean backscatter at nadir for the ocean surface in terms of an effective Lambertian reflectance by comparison of beach sand and ocean backscatter. Results were 16 and 24% reflectance on two missions where calibration was possible. The data are compared with prior laser backscatter measurements and the general literature on optical scattering from the ocean surface. (47 refs.)

110673 Target reflectance measurements for calibration of lidar atmospheric backscatter data. M.J.Kavaya, R.T.Menzies, D.A.Haner, U.P.Oppenheim, P.H.Flamant (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
Appl. Opt. (USA), vol.22, no.17, p.2619-28 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
Wavelength and angular dependence of reflectances and depolarization in the 9-11 μm region are reported for four standard targets: flowers of sulfur, flame-sprayed aluminum, 20-grit sandblasted aluminum, and 400-grit silicon carbide sandpaper. Measurements are presented and compared using a CW CO_2 grating-tunable laser in a laboratory backscatter apparatus, an integrating sphere, and a coherent pulsed TEA-CO_2 lidar system operating in the 9-11 μm region. Reflectance theory related to the use of hard targets to calibrate lidar atmospheric backscatter data is discussed. (21 refs.)

110674 Balloon-borne remote sensing of stratospheric constituents. D.G.Murcray, F.J.Murcray, A.Goldman, F.H.Murcray, J.J.Kosters (Phys. Dept., Univ. of Denver, Denver, CO, USA).
Appl. Opt. (USA), vol.22, no.17, p.2629-40 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
Remote-sensing techniques are generally considered as a means of obtaining data concerning the concentration species at altitudes not accessible to the observing platform; however, in the case of remote-sensing measurements of species in the lower stratosphere a considerable advantage in profile resolution can be obtained by making the measurements from balloons. Data concerning species of interest in the photochemistry of the ozone layer were obtained by balloon flights employing remote-sensing instruments making measurements in the wavelength region from the ultraviolet to millimeter wavelengths. The majority of the data were obtained using instruments to obtain data in the midinfrared wavelengths. Two techniques are generally used: solar absorption or atmospheric emission. Descriptions of the instrumentation used by the authors' group at the University of Denver to obtain data using both techniques are given. The techniques employed in the analysis of the data obtained with these instruments are discussed, and recent results are presented. The potential of both techniques for obtaining data of interest in the photochemistry of the ozone layer is also discussed. (7 refs.)

110675 Passive radiometry for vertical sounding from meteorological satellites. W.L.Smith (Dev. Lab., NOAA Nat. Environmental Satellite, Data & Information Service, Madison, WI, USA).
Appl. Opt. (USA), vol.22, no.17, p.2641-3 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
This paper summarizes the different types of passive radiometers flown on meteorological satellites for vertically sounding the lower atmosphere. (15 refs.)

110676 Balloon-borne diode-laser absorption spectrometer for measurements of stratospheric trace species. R.T.Menzies, C.R.Webster, E.D.Hinkley (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
Appl. Opt. (USA), vol.22, no.17, p.2655-64 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
A stratospheric trace species measurement concept is presented which utilizes tunable infrared diode lasers as sources for sensitive in situ absorption spectroscopy in selected wavelength regions. As an embodiment of this concept, the balloon-borne laser in situ sensor (BLISS) is a high-resolution absorption spectrometer designed to provide measurements of the concentrations of stratospheric species and their diurnal variations. The instrument uses second-harmonic detection of the absorption of tunable diode laser (TDL) radiation (3-30 μm) in a 1-km path length defined by a retroreflector lowered 0.5 km below the BLISS gondola. A He-Ne laser and co-aligned TV camera with CID imaging are used for retroreflector tracking under microprocessor control. Four TDLs will provide simultaneous measurements of molecular species in the 20-40 km altitude range, the predicted minimum-detectable mixing ratio at 30 km being typically ≤ 0.1 ppbv. (9 refs.)

110677 Tests of an inversion algorithm for spectrally resolved limb emission. R.D.Sharma (US Air Force Geophys. Lab., Hanscom Air Force Base, MA, USA), A.Zachor.
Appl. Opt. (USA), vol.22, no.17, p.2665-9 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
Spectrally resolved Earth limb radiance profiles were inverted to recover concentration and temperature profiles in the non-LTE altitude regime. These simulations used synthetic spectra for the optically thin NO fundamental band near 5.3 μm. The purpose of the study was to test a nonlinear inversion algorithm used previously to invert real data obtained in the Spectral Infrared Rocket Experiment. Specifically, the tests consisted of attempts to retrieve singly and doubly peaked excited density vs. altitude profiles and kinetic temperatures vs. altitude from the synthetic spectral data with and without added noise. A nonlinear inversion algorithm was used rather than the formal inverse of the Abel integral equation because it offers promise for species/bands that are not optically thin. (9 refs.)

110678 Atmospheric sounding from a geostationary satellite. W.P.Menzel (Space Sci. & Engng. Center, Univ. of Wisconsin-Madison, Madison, WI, USA), W.L.Smith, G.S.Wade, L.D.Herman, C.M.Hayden.
Appl. Opt. (USA), vol.22, no.17, p.2686-9 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
A case is presented to demonstrate the accuracy of the soundings from a geostationary platform with the visible infrared spin-scan radiometer atmospheric sounder (VAS) on GOES-5. VAS radiances for this case are consistent with TOVS high resolution infrared radiation sounder radiances. VAS temperature profile retrievals agree well with those observed by radiosonde. Initializing the retrieval process with ground-based Profiler data renders an

improved product. Time variations in the atmospheric state are readily discernible from VAS soundings at ~2-h intervals. (7 refs.)

110679 Assessment of relative error sources in IR DIAL measurement accuracy. N.Menyuk, D.K.Killinger (MIT Lincoln Lab., Lexington, MA, USA).
Appl. Opt. (USA), vol.22, no.17, p.2690-8 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
An assessment is made of the role the various error sources play in limiting the accuracy of infrared differential absorption lidar measurements used for the remote sensing of atmospheric species. An overview is presented of the relative contribution of each error source including the inadequate knowledge of the absorption coefficient, differential spectral reflectance, and background interference as well as measurement errors arising from signal fluctuations. (56 refs.)

110680 Spectral pattern recognition in IR remote sensing. A.S.Zachor (Atmospheric Radiation Consultants Inc., Acton, MA, USA).
Appl. Opt. (USA), vol.22, no.17, p.2699-703 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
The basic concepts and some of the methods of pattern classification are reviewed. The problem of detecting and quantifying a mixture of gases is discussed as an application of spectral pattern recognition to atmospheric IR remote sensing. (10 refs.)

110681 Method for investigating the abundance of elements in the Earth's interior. I.P.Nedyalkov (Inst. of Nuclear Res. & Energy, Bulgarian Acad. of Sci., Sofia, Bulgaria).
C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.5, p.619-22 (1983).
A method for the experimental determination of the distribution of the proton density and the neutron density within the Earth is proposed. These data, once elaborated, make it possible to study in an indirect way the abundance of elements in the Earth. The method described explores the possibilities of neutrino physics. It consists in measuring the attenuation of neutrino and antineutrino beams passed through the Earth in different directions. (15 refs.)

110682 Determination of sea surface temperatures and atmospheric correction values for infrared images on the base of data of the metrological satellite NOAA 5. I.Haupt, H.Billing, S.Jobst (Inst. fur Meteorologie, Freie Univ. Berlin, Berlin, Germany).
Contrib. Atmos. Phys. (Germany), vol.56, no.3, p.295-321 (1983).
Describes a method of deducing the sea surface temperatures and the effective atmospheric absorption from IR satellite measurements without detailed knowledge of the atmospheric conditions. Assuming that the sea surface temperature can be considered as more or less constant during a certain period, from the difference of the 'quasisimultaneously' measured temperatures the limb darkening effect can be deduced, i.e. the magnitude of the radiation absorbed in the atmosphere. Comparison with simple model calculations shows that, as a first approximation, the radiative transfer can be described as an effective absorption, increasing with the path length. (25 refs.)

110683 A method for evaluating the effect of crack geometry on the mechanical behavior of cracked rock masses. M.Oda (Dept. of Foundation Engng., Saitama Univ., Saitama, Japan).
Mech. Mater. (Netherlands), vol.2, no.2, p.163-71 (Aug. 1983).
Discontinuities like faults and joints (called cracks) are of widespread occurrence in rock masses in situ, with very complicated geological setting. The complexity, especially in their geometry, is no doubt a major obstruction to develop a useful theory for evaluating the mechanical behavior of cracked rock masses. An index measure (called fabric tensor) which has been introduced to show crack geometry is further discussed to see if it is useful for evaluating the mechanical behavior of rock masses in situ. Based on some acceptable simplification, an overall elastic compliance for cracked materials is successfully formulated in terms of the fabric tensor. Furthermore, with the help of geometrical probability, the fabric tensor is expressed in terms of in situ measurable quantities. These results strongly suggests that the concept of fabric tensor is useful in the analysis of cracked rock masses. (18 refs.)

110684 The IT method for the harmonic tidal prediction. F.Stravisi (Istituto Talassografico di Trieste, Trieste, Italy).
Boll. Oceanol. Teor. & Appl. (Italy), vol.1, no.3, p.193-204 (July 1983).
With respect to the seven major constituent tides M_2, S_2, N_2, K_2, K_1, O_1, P_1 commonly used in tidal prediction by means of the classical harmonic method, formulae are reported for the computation of the time dependent nodal factors f and of the arguments $V+u$. A fast converging Newton Fourier iterative procedure for the high and low waters computation is described. The related Fortran subroutines are listed. (5 refs.)

110685 Combination and comparison of various filtering techniques in processing gravity data. V.Bezvoda (Faculty of Sci., Charles Univ., Prague, Czechoslovakia), K.Segeth, C.Tomek.
Ann. Geophys. (France), vol.1, no.3, p.229-34 (May-June 1983).
The comparison of the linear filtering of gravity data in the space and wave number domains has shown a good agreement of both the ways employed. This is made particularly clear when processing in the wave number domain, the trend corresponding to a two-dimensional polynomial of low degree is subtracted in advance. In the space domain the filtering is easier, but the boundary region lost is too large. In the wave number domain, after subtracting the trend, the boundary region lost is substantially smaller. Moreover, this kind of filtering seems to be not only faster and easier to proceed, but also more flexible. Practical examples are presented of the gravity data measured in the sedimentary Vienna Basin. (19 refs.)

110686 VLF signal recognition by cross-spectral analysis. D.Jones (British Antarctic Survey, Cambridge, England), F.Lefeuvre, M.Parrot.
Ann. Geophys. (France), vol.1, no.3, p.253-8 (May-June 1983).
A method is described whereby magnetospheric VLF signals can be preprocessed and so reduce the amount of data that has to be telemetered (from satellites or remote Antarctic stations). The method entails the use of the cross-spectral phase, and in particular its stationarity with time, to extract the signal. The technique has been tested on natural VLF emissions recorded on GEOS 1 and the results illustrate that, not only do they support the predictions made on the basis of the earlier simulations, but they also allow the emissions to be viewed from a new perspective. They permit information to be obtained on the propagation characteristics of the waves which was not possible from the cross-spectral power or from the coherence function. The potential of the method for distinguishing signal from noise and for displaying wave propagation characteristics is illustrated using VLF hiss and chorus observed on GEOS 1. (8 refs.)

110687 High-throughput digital SAR processing. M.Jones (Mission & Tech. Coordination Office, European Space Operations Centre, Darmstadt, Germany), J.-C.Degavre, J.P.Guignard.
ESA J. (Netherlands), vol.7, no.2, p.145-62 (1983).
Work done within ESA on the definition of SAR-processing requirements and study of processing technology is reviewed. This work has been driven by the need for fast-delivery processing for the Synthetic-Aperture Radar (SAR) on ERS-1 (the first European remote-sensing satellite). The demands of ERS-1 SAR fast-delivery processing are described and compared with those for other remote-sensing missions. The computer loads involved are analysed by reference to results of theoretical analysis and benchmarking. The current status of processor selection for ERS-1 is described. (22 refs.)

110688 Amplitude calibration of spaceborne Synthetic Aperture Radars. D.N.Held (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
ESA J. (Netherlands), vol.7, no.2, p.163-7 (1983).
The quantitative use of Synthetic Aperture Radar (SAR) data requires that the imagery be well-calibrated. The paper discusses some of the fundamental problems that have been encountered in the past during attempts to calibrate SAR imagery, some recent successful experiments conducted with Seasat SAR data, and a proposed programme for the calibration and validation of the radar imagery from the forthcoming SIR-B SAR. (no refs.)

110689 Tunable diode laser systems for measuring trace gases in tropospheric air. H.I.Schiff, D.R.Hastie (York Univ., Downsview, Ontario, Canada), G.I.Mackay, T.Iguchi, B.A.Ridley.
Environ. Sci. & Technol. (USA), vol.17, no.8, p.352A-64 (Aug. 1983).
Describes the use of tunable diode laser absorption spectrometers for measuring nitrogen oxides in clean and polluted tropospheric air. The authors have used this spectrometer in a mobile system capable of in situ measurements of the oxides of nitrogen and other trace atmospheric gases. (27 refs.)

110690 Compensation of marine seismic data for the effects of highly variable water depth using ray-trace modeling—A case history. B.Dent (Cities Service Co., Tulsa, OK, USA).
Geophysics (USA), vol.48, no.7, p.910-33 (July 1983).
Variable water depth can cause severe degradation of marine seismic data. This paper presents a technique for correcting the effects of water depth variation and is a case history of applying the technique to a line of data from the Philippines offshore. The line crosses a deep submarine valley. (6 refs.)

110691 Geothermal prospecting with Shallo-Temp surveys. L.A.LeSchack (LeSchack Associates Ltd., Long Key, FL, USA).
Geophysics (USA), vol.48, no.7, p.975-96 (July 1983).
The Shallo-Temp survey is an inexpensive and rapid 'first look' geophysical technique that is useful in planning reconnaissance drilling geothermal exploration programs. The technique is based on making many soil temperature measurements at 2-m depths over a given exploration area and correcting these measurements for the effects of elevation and surface geologic and meteorologic conditions. The output from the model is the normally expected 2-m temperature for the given site at the date for which input data were provided. The difference between the measured and computed 2-m temperature data represents effects of geothermal heat flow. A Shallo-Temp residual map is compared both to a 2-m temperature map for a specific date (September, 1977) and to a mean annual 2-m temperature map for the Coso known geothermal resource area producing the same anomaly pattern in each case. (40 refs.)

110692 Butterworth dip filters. D.Hale, J.F.Claerbout (Dept. of Geophys., Stanford Univ., Stanford, CA, USA).
Geophysics (USA), vol.48, no.8, p.1033-8 (Aug. 1983).
Dip filters enable a geophysicist to discriminate between various seismic events on the basis of apparent dip. The frequency-wavenumber (w,k) domain seems an attractive domain to perform dip filtering because it permits the application of an arbitrary transfer function of dip. Seismic applications of dip filtering, however, seldom require the flexibility offered by the (w,k) domain; one may often be willing to sacrifice this flexibility to obtain features not possible with (w,k) domain filters, but readily available with time-space (t,x) domain filters. Examples are (1) time and space variability, (2) flexible treatment of computational grid boundaries, and (3) an efficient, recursive implementation. The authors describe a (t,x) domain dip filtering method with these features. (5 refs.)

110693 The resonant acoustic pulser—a continuous-frequency marine seismic source. H.C.Hardee (Geophys. Div., Sandia Nat. Labs., Albuquerque, NM, USA).
Geophysics (USA), vol.48, no.8, p.1082-9 (Aug. 1983).
A marine seismic source is described which produces a continuous low-frequency (10-100 Hz) harmonic signal. High acoustic power levels (~20 kW) are reached by using a resonant system. The seismic source has been successfully tested in lake and ocean environments. Geophysical applications are discussed and modifications are described which would allow the source to be operated in a swept-frequency mode. (12 refs.)

110694 Experience with the EM-60 electromagnetic system for geothermal exploration in Nevada. M.Wilt, N.E.Goldstein (Lawrence Berkeley Lab., Univ. of California, Berkeley, CA, USA), M.Stark, J.R.Haught, H.F.Morrison.
Geophysics (USA), vol.48, no.8, p.1090-101 (Aug. 1983).
Lawrence Berkeley Laboratory (LBL) conducted controlled-source electromagnetic (EM) surveys at three geothermal prospects in northern Nevada to test and demonstrate the applicability of LBL's EM-60 system to geothermal exploration. During the late summer and early fall of 1979, over 40 soundings were made in Panther Canyon (Grass Valley), near Winnemucca; Soda Lakes, near Fallon; and McCoy, west of Austin. The EM-60 is a frequency-domain system using three-component magnetic detection. For the surveys reported ±65 A was applied to a 100-m diameter four-turn horizontal loop, generating a dipole moment $>10^6$ mks over the frequency range 10^{-3} to 10^3 Hz. With such a source loop and a remote magnetic reference for noise cancellation, soundings were made at transmitter-receiver separations of up to 4 km over the frequency range of 0.05 to 500 Hz. This has yielded a maximum depth of exploration to 2 km or more, adequate for the purposes of the geothermal investigations. (24 refs.)

110695 Recent developments in the use of surface electrical methods for oil and gas exploration in the Soviet Union. B.R.Spies (Bur. of Mineral Resources, Canberra, Australia).
Geophysics (USA), vol.48, no.8, p.1102-12 (Aug. 1983).
In late 1979, the author visited the Soviet Union under the auspices of the Australia-USSR agreement on scientific cooperation, with the purpose of studying recent developments in electrical and electromagnetic (EM) methods. This paper presents a summary of the use and applications of those methods in oil and gas exploration, and includes a number of case histories. (22 refs.)

110696 Electrode configuration influence on resistivity measurements about a spherical anomaly. R.J.Lytle, J.M.Hanson (Lawrence Livermore Nat. Lab., Univ. of California, Livermore, CA, USA).
Geophysics (USA), vol.48, no.8, p.1113-19 (Aug. 1983).
The trade-offs involved with subsurface resistivity probing are studied for the case of a spherical anomaly. In particular, two-, three-, and four-electrode configurations are investigated. The three- and four-electrode configurations have similar results and have significantly better remote detection capabilities than does a two-electrode configuration. Cross-borehole probing is capable of detecting anomalous conditions at a greater range than is single-borehole probing. (17 refs.)

110697 Theoretical and experimental approaches to the geophone spurious frequency. Shi Jung Chen (AMF Geo Space Co., Houston, TX, USA), Ch.Dalton.
Geophys. Prospect. (Netherlands), vol.31, no.4, p.574-90 (Aug. 1983).
The geophone spurious frequency is modeled at the resonance of the planar motion of a spider spring carrying a moving mass. An analytic solution is found using the Castigliano method by assuming that the spring arm is a single-mode vibrating cantilever beam. The spring shape is found from this analysis. A dimensional analysis is used as an approximate method for general design. Based on the theoretical result, a rotational fixture and a translational fixture were designed for experimental purposes. A low-noise fixture and a phase-averaging technique provide the amplitude and spurious resonance in the frequency domain. (6 refs.)

110698 The autobalancer—an automatic system for the reduction of power-line interference with seismic signals. L.Ensing.
Geophys. Prospect. (Netherlands), vol.31, no.4, p.591-607 (Aug. 1983).
Since the early years of seismic surveying, field engineers and observers have been faced with the appearance of interference at power-line frequency (and harmonics) on seismic records. Such interference is picked up from the ground surface through electric leakage between geophone leads and ground. To minimize power-line interference, the autobalancer automatically performs a balancing procedure by adjusting two potentiometers on each channel. (4 refs.)

110699 Transformation of resistivity sounding measurements obtained in one electrode configuration to another configuration by means of digital linear filtering. A.T.Basokur (Ankara Univ., Besevler-Ankara, Turkey).
Geophys. Prospect. (Netherlands), vol.31, no.4, p.649-63 (Aug. 1983).
The technique of digital linear filtering is used for transformation of apparent resistivity data from one electrode configuration into another. Usually filter spectra are determined via the discrete Fourier transforms of input and output functions. In this paper, the transformation of the apparent resistivities is presented for four electrode configurations (Wenner, the two-electrode, Schlumberger, and dipole configurations). Sinc responses for determination of the derivative of apparent resistivities are given in analytical form. (12 refs.)

110700 Estimation of formation temperature from borehole measurements. M.N.Luheshi (Geophys. Res. Branch, BP Petroleum Dev. (Overseas), London.Ltd.,England).
Geophys. J. R. Astron. Soc. (GB), vol.74, no.3, p.747-76 (Sept. 1983).
A new numerical method is described for modelling the thermal disturbance around a borehole and a comparison is made with the commonly used line source model. The numerical model generally gives an estimate of the equilibrium formation temperature which is up to about 20 per cent higher than the 'Horner plot' method. The relaxation of the borehole temperature is sensitive to the contrast between the thermal properties of the drilling fluid and of the surrounding rock as well as to the disturbance time. The importance of vertical temperature gradients and fluid motion (both free convection in the borehole and flow in the formation) is also examined. It is found that vertical temperature gradients are unlikely to be important provided temperatures are measured more than 10 borehole radii above the bottom. Convective heat transfer can be important under some drilling conditions. (21 refs.)

110701 Sounding of the atmosphere with CW lidar. A.V.Sinyavskii.
Izv. Akad. Nauk Arm. SSR Fiz. (USSR), vol.17, no.1, p.39-41 (1982). In Russian.
A method for the investigation of atmospheric fogs using a CW laser is proposed. The processing of post-detector data allows one to discriminate the jamming of atmospheric aerosol return for small values of S/N ratio. (5 refs.)

110702 Augmenting LANDSAT MSS data with topographic information for enhanced registration and classification. K.Seidel, F.Ade (Inst. for Communication Technol., Zurich, Switzerland), J.Lichtenegger.
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.252-8 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
Deals with problems arising in the classification of LANDSAT MSS data from rugged terrain. A digital terrain model (DTM) was found to be useful in several ways. For registration by cross-correlation, mountain ridges were extracted from both a synthetic image based on the DTM and a LANDSAT image. Information from the DTM, from thematic maps, and meteorological data were all used as ancillary data to aid in rapid snow cover determination without direct ground control in a large catchment area. In addition it is shown that the use of the DTM not only allows the assessment of relative and absolute snow distribution within given elevation zones, but also permits the extrapolation of snow cover into areas partly covered with clouds. (17 refs.)

110703 The Thematic Mapper—an overview. J.L.Engel (Santa Barbara Res. Center, Goleta, CA, USA), O.Weinstein.
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.258-65 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
The Thematic Mapper (TM) is a second-generation Earth resources sensor built by Hughes Aircraft Company for NASA for the LANDSAT series of spacecraft. The TM was placed in orbit aboard the LANDSAT-D spacecraft in July of 1982. Its predecessor, the Multispectral Scanner (MSS) has flown on LANDSAT's 1 through 3 and accompanies the TM on LANDSAT-D. The need for improved performance was recognized prior to the launch of the first MSS on LANDSAT-1 in 1972. The performance specifications for the TM were formulated to produce performance improvements in the next generation sensor. This paper will provide an overview of TM and will briefly discuss the LANDSAT-D mission and orbit, TM design, instrument performance, and program status. (no refs.)

110704 On the sampling problem in radiation budget studies. K.T.Kriebel, A.E.Pietrass (Deutsche Forschungs -und Versuchsanstalt fur Luft -und Raumfahrt e.V., Oberpfaffenhofen, Germany).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.271-8 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
The radiation budget is the difference of downwelling and upwelling flux densities at a reference surface, whereas the quantity measured by narrow field of view instruments is the directional radiance. Insufficient knowledge of its angular anisotropy causes errors in the derived radiation budget. A new formulation is presented of the constraints in sampling the angular directions of the hemisphere over a mesoscale target area, introduced by scan patterns and by orbit repeat cycles. Comparison by simulation of line scanner, conical scanner (CSR), and Nimbus-7 ERB scanner in orbits with short and long repeat cycle reveals the latter orbit and the CSR as best suited to sample all directional classes. (21 refs.)

110705 Mapping and analysis of aerial conductivity measurements from INPUT system over geothermal areas. V.S.Jordon (Geo-Centers, Inc., Newton, MA, USA), K.U.Sivaprasad, D.V.Smith.
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.278-84 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
Remotely sensed electromagnetic data taken with an INPUT system for the US Geological Survey in aerial surveys over a known geothermal resource area have been reduced and plotted in a gray scale format for two- and three-dimensional projections of the apparent subsurface conductance. The apparent conductance is calculated using both the channel ratio method and the theoretical two-layer model of the Earth. Matching the survey data to the two-layer model gave good results consistent with the ratio method of apparent conductance calculation and permitted the construction of maps of horizontal slices of apparent conductance at different depths into the Earth, from one to fifty metres. The channel ratio and horizontal slice maps of apparent conductance give a picture of the apparent conductance which is consistent with known topographical features of the regions. (5 refs.)

110706 Variation of the microwave brightness temperature of sea surfaces covered with mineral and monomolecular oil films. H.-J.Blume (NASA Langley Res. Center, Hampton, VA, USA), H.Huhnerfuss, W.Alpers.
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.295-300 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
Airborne microwave radiometer measurements over mineral and monomolecular oil films and adjacent clean sea surfaces are reported. An artificial crude-oil spill experiment in the New York Bight area showed a brightness temperature increase of the sea surface at 1.43 GHz as expected from a multilayered system with different dielectric constants. However, a monomolecular surface-film experiment with oleyl alcohol conducted in the North Sea during MARSEN in 1979 showed a strong brightness temperature depression at 1.43 GHz and no change in brightness temperature at 2.65 GHz. It is postulated that the monomolecular layer, because of its physical and chemical properties, polarized the underlying water molecules so strongly that the emissivity decreased from 0.31 to 0.016. It is estimated that the effective dielectric constant changed from 90 to 5.2×10^4. Because these phenomena occurred at 1.43 GHz it may be concluded that this frequency is very close to the center of a new anomalous dispersion region resulting from a restructuring of the water layer below the surface film. (17 refs.)

110707 Improvement of moisture estimation accuracy of vegetation-covered soil by combined active/passive microwave remote sensing. F.T.Ulaby, M.C.Dobson, D.R.Brunfeldt (Remote Sensing Lab., Univ. of Kansas Center for Res. Inc., Lawrence, KS, USA).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.300-7 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
The measured effects of vegetation canopies on radar and radiometric sensitivity to soil moisture are compared to first-order emission and scattering models. The models are found to predict the measured emission and backscattering with reasonable accuracy for various crop canopies at frequencies between 1.4 and 5.0 GHz, especially at angles of incidence less than 30°. The vegetation loss factor $L(\theta)$ increases with frequency and is found to be dependent upon canopy type and water content. In addition, the effective radiometric power absorption coefficient of a mature corn canopy is roughly 1.75 times that calculated for the radar at the same frequency. Comparison of an L-band radiometer with a C-band radar shows the two systems to be complementary in terms of accurate soil moisture sensing over the extreme range of naturally occurring soil-moisture conditions. (14 refs.)

110708 Amplitude and phase errors involved in retrieving depolarized radar cross section measurements. A.J.Blanchard, R.W.Newton, B.R.Jean (Remote Sensing Center, Texas A&M Univ., College Station, TX, USA).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.314-19 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
The response of radar systems to linearly polarized (both like and cross polarized) interaction processes associated with Earth/land targets is studied theoretically. Particularly disconcerting is the general lack of agreement near nadir between depolarized radar data and the theoretical models which attempt to describe these processes. In this paper consideration is given to the geometry of the measurement situation and the nonideal nature of realistic antennas in an attempt to quantify possible measurement system error. The results indicate that induced system error can account for several dB of error in the depolarized measurement. These errors are most significant at the nadir measurement configuration. (14 refs.)

110709 Atmospheric water-vapor profiling by ground-based radiometry at 22 and 183 GHz. J.I.H.Askne, B.G.Skoog (Dept. of Electron Phys., Chalmers Univ. of Technol., Gothenburg, Sweden).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.320-3 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
The possibility to determine water-vapor profiles by combining observations at 21.0 and 31.4 GHz with observations at frequencies near the 183.3-GHz resonance line has been investigated. It is demonstrated that the accuracy of the retrieved profiles will be improved in the height interval 0 to 2 km. In this height interval the presence of inversion layers is one of the main uncertainties. As an alternative to 183-GHz observations, an active sensor can be used to indicate the presence of an inversion layer. It is shown that the improvement of the accuracy would then be of the same order as obtained with a 183-GHz system. (14 refs.)

110710 Synthetic aperture radar imaging from an inclined geosynchronous orbit. K.Tomiyasu, J.L.Pacelli (General Electric Co., Valley Forge Space Center, Philadelphia, PA, USA).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.324-9 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
Images of Earth can be produced with an assumed synthetic aperture radar (SAR) on a satellite platform undergoing a nutating relative motion from geosynchronous altitude. From a 50° inclined circular orbit, the contiguous United States can be imaged in about 3 h of segmented operation at 100-m resolution with 4-azimuth-look averaging. The 2450-MHz transmitter radiates

1312 W of average power from a steerable 15-m-diam antenna. The SAR can image daily an area bounded longitudinally and latitudinally. (14 refs.)

110711 Remote sensing of soil moisture: recent advances. T.J.Schmugge (Hydrological Sci. Branch, NASA Goddard Space Flight Center, Greenbelt, MD, USA).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.336-44 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
In the past few years there have been many advances in the understanding of microwave approaches for the remote sensing of soil moisture. These advances include a method for estimating the dependence of the soil's dielectric constant on its texture; the use of percent of field capacity to express soil moisture magnitudes independently of soil texture; experimental and theoretical estimates of the soil moisture sampling depth; models for describing the effect of surface roughness on the microwave response in terms of surface height variance and the horizontal correlation length; verification of the ability of radiative transfer models to predict the microwave emission from soils; and experimental and theoretical estimates of the effects of vegetation on the microwave response to soil moisture. This research has demonstrated that it is possible to remotely sense soil moisture in the surface layer of the soil (about 0-5 cm). In addition there have been simulation studies indicating how remotely sensed surface soil moisture may be used to estimate evapotranspiration rates and root-zone soil moisture. (42 refs.)

110712 A compact high-resolution Michelson interferometer for passive atmospheric sounding (MIPAS). P.Burkert (Kayser-Threde GmbH, Munich, Germany), F.Fergg, H.Fischer.
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.345-9 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
More precise information on the chemistry, dynamics, and energy budget of the middle atmosphere can be derived from globally and simultaneously measured concentration profiles of a substantial number of atmospheric trace gases. Such a data base can be obtained from infrared limb spectra which are recorded by spaceborne instruments. Fourier transform spectrometers are especially appropriate for such a task. In this paper are discussed characteristic features and performance parameters of a compact high-resolution (0.05 cm^{-1}) rapid-scanning (1 s) interferometer for measurements in the 2 to 15-μm region. Technical data of a cryogenic version as well as of an uncooled satellite instrument are presented. (17 refs.)

110713 The Ocean Color Experiment (OCE) on the second orbital flight test of the Space Shuttle (OSTA-1). H.van der Piepen (DFVLR, Inst. fur Optoelektronik, Oberpfaffenhofen, Germany), H.H.Kim, W.D.Hart, V.Amann, H.Helbig, A.F.G.Fiuza, M.Viollier, R.Doerffer.
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.350-7 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
The Ocean Color Experiment was one of the six remote-sensing experiments which for the first time were launched and successfully operated on board of the second flight of the Space Shuttle during November 1981. The experiment consists of a multispectral image scanner dedicated to the measurement of water color and its interpretation in terms of major water constituents and circulation patters. The objectives of the experiment, the test site selection, and associated activities are described. The actual mission and results of an initial data analysis is discussed. (13 refs.)

110714 The dielectric properties of wet materials. G.Paul de Loor (Phys. Lab. TNO, The Hague, Netherlands).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.364-9 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
In microwave remote sensing, knowledge of the dielectric properties of the materials observed (vegetation, soils) is important for the interpretation of the recorded reflection or emission and for the design of models for this reflection or emission. Although there exists no simple law which describes the properties of a heterogeneous system when the properties of its components are known, boundaries can be indicated for the permittivity of such a system. Heterogeneous systems containing water, such as wet soils and plant material, have very complex dielectric properties due to the role of the conductivity. However, at the higher microwave frequencies, in particular above the *S*-band, these conductivity effects play only a minor role and the free water is most important. By knowing the permittivity of wet materials the penetration depth can be determined. In all practical cases this depth is smaller than the wavelength used for the observations. (22 refs.)

110715 Comparison of several techniques to obtain multiple-look SAR imagery. F.-K.Li (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA), C.Croft, D.N.Held.
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.370-5 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
Synthetic aperture radar imagery is contaminated by coherent speckle noise. In order to improve interpretability, multiple-look images are usually generated. In this paper, the authors examine the performance of several classes of techniques to generate such multiple-look imagery. The detailed impulse responses and the signal-to-speckle noise ratios obtained by the various techniques are presented. It is found that by using several types of image domain filters, the signal-to-speckle noise ratio can be improved over the conventional discrete mixed-integrator while keeping the equivalent rectangular resolution constant. (13 refs.)

110716 Remote sensing of wetlands. M.K.Butera (Earth Resources Lab., NASA/Nat. Space Technol. Labs., NSTL Station, MS, USA).
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.383-92 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
Demonstrates three examples of applying remote sensing technology to the delineation of wetlands in the United States. First, the results of a technique to identify roseau cane (Phragmites communis) using LANDSAT and aircraft MSS data are presented. Approximately 9700 ha. of Phragmites communis were identified in the Mississippi River delta using LANDSAT data. Second, the results of a technique to identify wetland communities, principally mangroves, in Florida using LANDSAT and aircraft MSS are presented. A cost analysis of the remote versus conventional ground-survey technique is provided. The LANDSAT MSS average classification accuracy for mangroves only versus all classes were 87 percent and 74 percent, respectively. The third example presents the results of a technique to delineate surface cover types in the southeast tidal/riverine system of the Savannah River. (12 refs.)

110717 Simulation of spaceborne stereo radar imagery: experimental results. V.H.Kaupp (Dept. of Electrical Engng., Univ. of Arkansas, Fayetteville, AR, USA), L.C.Bridges, M.A.Pisaruck, H.C.Macdonald, W.P.Waite.
IEEE Trans. Geosci. & Remote Sensing (USA), vol.GE-21, no.3, p.400-5 (1982). (1982 International Geoscience and Remote Sensing Symposium (IGARSS '82), Munich, Germany, 1-4 June 1982).
Computer simulation of radar imagery was used to investigate spaceborne stereo radar. The major conclusions reached are that stereo pairs representing different angles of incidence with the same look-direction appear best and that the angles of incidence and stereo intersection angle be matched to the slope and relief of terrain. A parametric tradeoff analysis was performed for eleven different angles of incidence over three different model areas. The eleven angles spanned the range from small- to large-incidence angles. The three model areas were selected as typical of relatively flat, moderately rough, and mountainous terrain. The stereo pair judged best for each model area are included. (20 refs.)

110718 Automatic AF-demagnetiser using a two-axis spin magnetometer. R.Hummervoll (Dept. of Geophys., Univ. of Bergen, Bergen, Norway).
J. Phys. E (GB), vol.16, no.9, p.888-91 (Sept. 1983).
A description of an automatic instrument is given, in which demagnetisation and subsequent measurement of the partially demagnetised rock sample is performed at the same field-free space. The rock samples are measured by a two-axis spin magnetometer which gives the three orthogonally magnetic components directly during the spin without the need to turn the sample in its holder. (4 refs.)

110719 Sea surface winds from Sun glitter observations. L.Wald, J.M.Monget (Ecole Nat. Superieure des Mines de Paris, Valbonne, France).
J. Geophys. Res. (USA), vol.88, no.C4, p.2547-55 (20 March 1983). [received: Sept. 1983]
Solar light reflected by the surface of the sea depends strongly on the sea state which is driven by the wind. The relationship between the reflected light and wind speed is described by the well-known model of Cox and Munk (1954, 1955). Using their model, a method is derived for the retrieval of the synoptic field of wind magnitude from measurements of the glitter pattern from space. This method is applied to data obtained by the TIROS-N satellite series. Comparison of the wind estimated in this way and the wind derived from isobaric charts shows very close agreement. The method is simple and has application over broad geographic areas. (26 refs.)

110720 The effect of oceanic whitecaps and foams on pulse-limited radar altimeters. Q.A.Zheng, V.Klemas (Coll. of Marine Studies, Univ. of Delaware, Newark, DE, USA), G.S.Hayne, N.E.Huang.
J. Geophys. Res. (USA), vol.88, no.C4, p.2571-8 (20 March 1983). [received: Sept. 1983]
Based on electromagnetic field theory of stratified media, the microwave reflectivity of a sea surface covered by whitecaps and foams at 13.9 GHz was computed. The computed results show that the reflectivity declines with increasing thickness of foams. The reflectivity of the sea surface without any whitecaps or foams is 0.6066 (20°C, *S*:35 per mille), but it will be less than 0.15 when the thickness of foam cover is more than 0.3 cm. While gathering the data of whitecap and foam coverage in situ and reviewing whitecapping models, it can be shown that the effect of oceanic whitecaps and foams on the measurement results of a pulse-limited radar altimeter working at high frequencies will not be negligible in high sea state conditions. (41 refs.)

110721 High-resolution spectral estimation of synthetic aperture radar ocean wave imagery. P.L.Jackson (Geological Sci. Dept., Univ. of Michigan, Ann Arbor, MI, USA), R.A.Shuchman.
J. Geophys. Res. (USA), vol.88, no.C4, p.2593-600 (20 March 1983). [received: Sept. 1983]
A new two-dimensional spectral estimation procedure, termed semicausal, is applicable to analysis of ocean gravity waves. Spectral estimates of both reference functions and actual synthetic aperture radar data of ocean waves have been generated using semicausal techniques and compared to fast Fourier transform estimates of identical data sets. The semicausal method can successfully generate spectral estimates of truncated data sets and data sets with two closely spaced frequency components. The semicausal estimate is sensitive to the autoregressive order and exhibits spectral splitting in some cases. Its noise sensitivity is similar to that of the Fourier transform. (15 refs.)

110722 GPS aiding of ocean current detemination. S.N.Mohan (Navigation Systems Section, Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
J. Astronaut. Sci. (USA), vol.31, no.2, p.281-313 (April-June 1983).
In situ ocean current measurements involving the use of shipborne acoustic profilers are dependent on accurate ship velocity information. Acoustic profilers permit measurement of the horizontal water velocity relative to the ship; however, absolute current velocity can be obtained only if the velocity of the ship relative to an Earth-fixed coordinate reference is known. Available navigation sources such as LORAN-C, Transit and Omega suffer from limitations in coverage; and with the exception of Transit, in accuracy as well. The NAVSTAR Global Positioning System (GPS) has the potential to extend coverage as well as improve navigational precision. GPS user application in the marine environment is as yet new and is a subject of current investigation. The author presents an accuracy analysis using a shipboard GPS receiver and coverage from the existing constellation of GPS navigation satellites. (20 refs.)

110723 The WPL profiler: a new source of mesoscale observations. P.K.James (Meteorological Office Radar Res. Lab., RSRE, Malvern, England).
Meteorol. Mag. (GB), vol.112, no.1333, p.229-36 (Aug. 1983).
A ground-based system being developed at the Wave Propagation Laboratory in Boulder, Colorado, is able, unmanned, to provide atmospheric profiles up to tropospheric heights. The output from this system is continuous in time and thus is potentially a useful source of information for short-period forecasters. (12 refs.)

110724 Oscillations of moored current meters and their effect on the measurement of current variables. V.M.Kushnir, V.I.Remchukov (Marine Hydrophys. Inst., Acad. of Sci., Sevastopol, Ukrainian SSR).
Oceanology (USA), vol.22, no.2, p.239-44 (1982). Translation of: *Okeanologiya (USSR),* vol.22, no.2 (1982). [received: Aug. 1983]
A recorder of the relative current velocity and angular deviations from the longitudinal, transverse and vertical axes of the current meter is described. Methods of statistical data processing are analysed in order to determine the contribution of different components to the total variance of the velocity measuring error. Results of measurements performed at different depths in the Caribbean Sea are discussed. (9 refs.)

110725 Aircraft-borne lightning sensor. W.L.Wolfe (Optical Sci. Center, Univ. of Arizona, Tucson, AZ, USA).
Opt. Eng. (USA), vol.22, no.4, p.456-9 (July-Aug. 1983).
Describes an instrument that has been used to measure the spatial and temporal distributions of lightning strokes as seen from a high-altitude aircraft platform. It consists of two separate sensors. One has a lens, selectable filters, and a 50×50 element array of photodiodes. The second has an identical lens, filters, and a single detector that covers the same total field of view. (4 refs.)

110726 Tradeoffs among several synthetic aperture radar image quality parameters: results of a user survey study. F.K.Li, M.L.Bryan (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
Photogramm. Eng. & Remote Sensing (USA), vol.49, no.6, p.791-803 (June 1983).
A synthetic aperture radar (SAR) is a complex remote sensor. In such remote sensing systems there are a number of options available for tradeoffs by the system designer. In this study the author analyzes the effects of adjusting the 'number of multiple looks' (i.e. the amount of incoherent averaging used in producing the imagery), the 'resolution' (i.e. the number of quantization levels per sample of the raw SAR signal). Several scenes obtained by the Seasat SAR were processed in a variety of ways and studied by a group of interpreters. Their responses were tabulated with respect to the particular scene and the different processing parameters which were used to produce the images. It is concluded that the relative importance for image interpretation is, in decreasing order, resolution, number of multiple looks, and number of bits. (18 refs.)

110727 Spectral characterization of the Landsat-4 MSS sensors. B.L.Markham, J.L.Barker (NASA, Goddard Space Flight Center, Greenbelt, MD, USA).
Photogramm. Eng. & Remote Sensing (USA), vol.49, no.6, p.811-33 (June 1983).
Relative spectral response data for the Landsat-4 and Landsat-4 backup multispectral scanner subsystems (MSS), the protoflight and flight models, respectively, are presented and compared to similar data for the Landsat 1, 2, and 3 scanners. Channel-by-channel (six channels per band) outputs for soil and soybean targets were simulated and compared with each band and between scanners. The two Landsat-4 scanners proved to be nearly identical in mean spectral response but they exhibited some differences from the previous MSS's. (6 refs.)

110728 A weather radar correction procedure for real-time estimation of surface rainfall. C.G.Collier, P.R.Larke, B.R.May (Meteorological Office Radar Res. Lab., Malvern, England).
Q. J. R. Meteorol. Soc. (GB), vol.109, no.461, p.589-608 (July 1983).
Several sources of error have been identified in measuring rainfall by radar. In this paper, the authors discuss these sources of error as they affect the calibration of a radar system using raingauge data. Present calibration techniques are considered, and the need for procedures based upon a knowledge of the structure of precipitation systems is noted. Finally, a new procedure is described, and its performance assessed for a number of cases of frontal and convective rainfall. (21 refs.)

110729 One possibility for predicting the Delingier effect from solar radio-emission data. L.P.Morozova (Inst. of Appl. Geophys., USSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.10, p.795-7 (Oct. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.10, p.1115-18 (Oct. 1982). [received: Sept. 1983]
The possibility is considered of predicting the Delingier effect seven days in advance from the criterion of an excess of the current level of radio-emission intensity at $\lambda=3.2$ cm over a floating threshold which depends on the solar activity index $F_{10.7}$. The prediction is quasioptimal, minimizing the total losses due to omission and spurious detection of the effect, and based on data of 1978-1981 it provides a probability of correct detection on the order of 90%. (6 refs.)

110730 Remote radio determination of the altitude gradient of the temperature in the near-surface layer of the atmosphere. S.A.Zhevakin (Radiophys. Sci. Res. Inst., USSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.10, p.797-806 (Oct. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.10, p.1119-30 (Oct. 1982). [received: Sept. 1983]
A procedure is proposed for the determination of the value of the near-surface temperature gradient of the atmosphere a averaged over the near-surface layer of the atmosphere (several hundred meters thick) from the brightest temperatures at two viewing angles. It is shown that the optimal absorption line for making the measurements is the $\lambda\sim5$ mm ($\nu\simeq59$-62 GHz) oxygen multiplet. It is noted that the accuracy of the determination of the quantity a by the proposed procedure is several times higher than by the usual procedure of recovering the temperature distributions of the atmosphere at frequencies $a=53$-55 GHz. (17 refs.)

110731 The measurement of atmospheric extinction and brightness temperature at millimeter wavelengths. S.A.Pelyushenko (Sci.-Res. Inst. of Radiophys., USSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.11, p.906-13 (Nov. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.11, p.1269-78 (Nov. 1982). [received: Sept. 1983]
Discusses a technique for determining the total vertical extinction in the atmosphere (in the 6-8 mm band) which permits both radio emission of the Earth and anisotropy of the side lobes of an antenna beam to be correctly taken into account. The author derives the dependence of the total vertical extinction in the atmosphere on the absolute humidity near ground level from measurements at wavelengths of 6.3, 6.7, and 8.6 mm. (13 refs.)

110732 Method of measuring the vertical ozone distribution by an optical method on meteorological rockets. N.I.Brezgin (Central Aerological Obs., USSR).
Sov. Meteorol. & Hydrol. (USA), no.4, p.79-84 (1982). Translation of: *Meteorol. & Gidrol. (USSR)*, no.4, p.100-5 (1982).
The main components of photometers and a method of measuring the vertical ozone distribution using meteorological rockets MR-12 and M-100 by an optical method are described. The atmospheric ozone content is calculated by several methods. The error of measuring the vertical ozone distribution by the optical method is estimated theoretically. To check the theoretical estimate, the results obtained in different spectral intervals on one meteorological rocket and in two launches of meteorological rockets conducted with an hour interval were compared. (16 refs.)

110733 Clear weather laser radar. C.E.Harris (Equipment Dev. Labs., Raytheon Co., Sudbury, MA, USA), J.A.Dunkin.
Electro/81 Conference Record, New York, USA, 7-9 April 1981 (El Segundo, CA, USA: Electron. Conventions 1981), p.34/3/1-8
This paper describes an airborne LIDAR system designed for the measurement of atmospheric velocities under conditions of clear weather from ground level to jet transport flight levels. The design of the CO_2 MOPA transmitter and filter bank processor are discussed, performance evaluations of the system are presented and some of the results of atmospheric measurements are presented. (2 refs.)

110734 Effects of the atmosphere on image resolution in microwave radiometry. G.d'Auria, D.Solimini (Istituto di Elettronica, Univ. di Roma, Roma, Italy).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.259-67
Effects of the atmosphere and the radiometer antenna on the attainable image resolution has been analyzed. The use of a de-convolution process to improve resolution is discussed together with errors introduced when correcting for atmospheric effects. Accuracy of resolution is taken into account following the Backus-Gilbert approach and a trade off between resolution and noise suppression is sought. Errors caused by the atmosphere are derived for realistic meteorological conditions. (12 refs.)

110735 Mesopheric water vapour measured with an airborne sensor. G.K.Hartman (Max-Planck-Inst. fur Aeronomie, Lindau, Germany), K.F.Kunzi, E.Lobsiger.
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.269-71
A mm-wave radiometer measuring the thermal emission from rotational transitions of the H_2O-molecule is well suited to obtain height information on the mixing ratio of water vapour in the stratosphere and mesosphere. The strong 183 GHz resonance (wavelength ~1.6 mm) allows sufficient signal to noise ratio for relatively short integration times of minutes, however the large amount of water vapour in the troposphere requires an observing altitude at or near the tropopause. The microwave sensor used on the German meteorological research aircraft Falcon in several flights during 1982 permits to retrieve the water vapour distribution between 30 and 80 km. The preliminary data analysis shows typical volume mixing ratios below 3 ppm above 50 km with no significant maximum at the stratopause as found with ground based 22 GHz measurements. (9 refs.)

110736 Radiometric sensing of the atmospheric boundary layer. P.Ciotti, A.Silbermann (Istituto di Elettronica, Univ. di Roma, Rome, Italy), D.Solimini, E.R.Westwater.
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.281-8
Radiometry is a convenient and powerful remote sensing technique in meteorology. Sufficiently sensitive instruments operated on suitable wavelength bands are able to sense small scale fluctuations of meteorological variables and the fast temporal response makes radiometry an attractive technique for remotely monitoring the boundary layer of the atmosphere. To evaluate ground-based radiometry for boundary layer observations, an experiment was carried out at the NOAA Boulder Atmospheric Observatory, where a 300 m instrumented tower provides adequate atmospheric truth. The output of an infrared radiometer set at the base of the tower was recorded on several days and with different meteorological conditions, together with data collected by the sensors at the various levels of the tower. From the temporal data series correlation is apparent between the characteristics of the radiometer output and the structure of the atmospheric boundary layer. (12 refs.)

110737 ART and SIRT correction factors in geotomography. C.A.Balanis, H.W.Hill, K.A.Freeland (Dept. of Electrical Engng., West Virginia Univ., Morgantown, WV, USA).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.335-9
A new correction factor is introduced which, when utilized with the iterative reconstruction techniques of the ART and SIRT, provides images of high resolution. In addition, the utilization of the newly formed correction factor results in reconstructions which converge at a faster rate. The reconstruction quality of each image is judged by its corresponding Euclidean distance. (9 refs.)

110738 Stability improvements in geotomographic inversion methods. R.Radcliff (Dept. of Electrical & Computer Engng., Ohio Univ., Athens, OH, USA), C.A.Balanis, H.W.Hill.
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.341-6
The accuracy, validity, and range of application of geophysical tomography (geotomography) has recently been significantly improved by the incorporation of refraction and first-order reflection into the inversion process. This is done by the means of an iterative refinement scheme, which exhibits stability problems under certain conditions. In this paper, the stability improvements of selective smoothing and path elimination are introduced which, along with guidelines for their application developed through experience with many computer simulations, results in a much more stable geotomographic technique. Several examples of reconstructions obtained by this technique are given and compared with those obtained by traditional straight-line geotomography. (11 refs.)

110739 On electromagnetic methods in geophysical probing. V.Hansen (Inst. fur Hoch- und Hochstfrequenztech., Ruhr-Univ. Bochum, Bochum, Germany).
Wave Propagation and Remote Sensing. Proceedings of URSI Commission F Symposium, Louvain-la-Neuve, Belgium, 9-15 June 1983 (Paris, France: ESA 1983), p.399-404
The electromagnetic field is analysed for a wire antenna above a stratified structure as a model of the Earth. For the current on the wire an integral equation is formulated using the Green's function of the structure. The complete set of equations for the Green's function are discussed and solved including the effect of surface and leaky waves. The integral equation is solved by the method of moments. Inferred from the current the input impedance, the mutual coupling of two antennas and the field in the layers are discussed and interpreted in terms of the structure parameters. (12 refs.)

94.00 AERONOMY AND SPACE PHYSICS

94.10 PHYSICS OF THE NEUTRAL ATMOSPHERE

(for planets, see 96.30)

110740 Perturbations of the upper atmosphere caused by flow over an isolated mountain. N.N.Pertsev.
Izv. Akad. Nauk SSSR Fiz. Atmos. & Okeana, vol.19, no.6, p.570-5 (June 1983). In Russian. English translation in: *Izv. Acad. Sci. USSR Atmos. & Oceanic Phys. (USA)*
The steady flow over an isolated mountain for uniform background fields of temperature and wind is examined using linear theory. An asymptotic solution for lee waves is obtained. For isolated mountains of specific form a map of lines of equal wave amplitudes and wave phases on the sphere of 100 km radius is constructed. The solution is compared with two-dimensional one and with three-dimensional solution obtained with the hydrostatic assumption. (12 refs.)

110741 Neutral and ion gas heating by auroral electron precipitation. M.H.Rees (Geophys. Inst., Univ. of Alaska, Fairbanks, AK, USA), B.A.Emery, R.G.Roble, K.Stamnes.
J. Geophys. Res. (USA), vol.88, no.A8, p.6289-300 (1 Aug. 1983).
The physical and chemical processes responsible for neutral gas heating resulting from energetic electron bombardment of the atmosphere are quantitatively described. The neutral heating efficiency, defined as the local heating per unit energy deposition, is evaluated for a range of typical auroral electron spectra, and it is shown that the altitude profile of the efficiency is independent of the electron spectrum. The efficiency is sensitive to the neutral atmosphere (composition, density, temperature) but differences can be minimized by adopting a pressure coordinate in place of the altitude. Over half the energy input rate associated with energetic particle precipitation goes into neutral heating, while less than 5% leads to ion heating. The coupling between particle precipitation and joule heating is discussed, and a parameterized Pedersen conductance curve is presented. (38 refs.)

110742 The response of thermospheric atomic nitrogen to magnetic storms. M.J.Engebretson (Dept. of Phys., Augsburg Coll., Minneapolis, MN, USA), K.Mauersberger.
J. Geophys. Res. (USA), vol.88, no.A8, p.6331-8 (1 Aug. 1983).
Neutral composition data obtained by the open-source neutral-mass spectrometer on the polar orbiting Atmosphere Explorer D satellite during the periods October 31 to November 15, 1975, and January 5 to 15, 1976, are used to characterize the response of thermospheric atomic nitrogen densities to geomagnetic activity. The results support current models showing that N is produced and transported out of the auroral zone during geomagnetic disturbances. (39 refs.)

110743 Rocket-based investigations of $O(^3P)$, $O_2(a^1\Delta_g)$ and OH* ($\nu=1$, 2) during the solar eclipse of 26 February 1979. W.R.Pendleton,Jr., K.D.Baker, L.C.Howlett (Utah State Univ., Logan, UT, USA).
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.479-91 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
Discusses the results of an in situ investigation of selected atmospheric minor constituents above Red Lake, Ontario, Canada, during the total solar eclipse of 26 February 1979. The species $O(^3P)$ and $O_2(a^1\Delta_g)$ were investigated at about 25 min before second contact, and OH* was examined at totality. Measurements were carried out with instrumentation aboard sounding rockets and provided useful information on these species over a range of altitudes which included the mesosphere and the lower thermosphere in the former case and a narrow region in the vicinity of the mesopause in the latter case. (42 refs.)

110744 Seasonal variation of solar atmospheric tides at meteor heights. T.Tsuda, T.Aso, S.Kato (Radio Atmospheric Sci. Center, Kyoto Univ., Gokanosho, Uji, Japan).
J. Geomagn. & Geoelectr. (Japan), vol.35, no.3, p.65-86 (1983).
Systematic observation with the Kyoto meteor radar (35°N, 136°E) has been continuing since the end of 1977. A seasonal variation of diurnal and semidiurnal solar atmospheric tides at meteor heights has been studied by using meteor radar data. Monthly average behaviours of these tidal components have been summarized for the period from March 1979 to November 1980. Vertical profiles and harmonic dials of these components have been investigated in comparison with other interference between propagating the evanescent modes. The evanescent mode becomes dominant in summer, while the propagating mode appears in winter. As for the semidiurnal tide, the $S_{2,2}$ mode is fundamental in summer, and the $S_{2,4}$ mode becomes apparent in winter. (24 refs.)

110745 Noctilucent clouds over Western Europe during 1982. D.H.McIntosh, M.Hallissey (Dept. of Meteorology, Univ. of Edinburgh, Edinburgh, Scotland).
Meteorol. Mag. (GB), vol.112, no.1333, p.245-9 (Aug. 1983).
Summarizes the observations of noctilucent cloud over Western Europe during 1982, as reported to the Department of Meteorology, University of Edinburgh. Brief notes of the displays enlarge on the facts listed i.e. forms discernible, tropospheric cloud conditions, photographs and sketches available. Co-ordinates of the observing stations and selected details of elevation and azimuth are presented. Routine hourly observations were made at 12 Meteorological Stations in the United Kingdom and at Reykjavik in Iceland when darkness permitted. (no refs.)

110746 Dynamics of the Earth's thermosphere. R.G.Roble (Nat. Center for Atmospheric Res., Boulder, CO, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.217-33 (March 1983).
This review covers the progress made in understanding thermospheric dynamics based on work published from 1979 to 1982 with some overlap of work published in 1978. Although all aspects of thermospheric dynamics are considered, emphasis is placed on the global circulation, temperature, and compositional structure of the thermosphere. (290 refs.)

110747 Neutral and ion composition of the thermosphere. D.G.Torr (Centre for Atmospheric & Space Sci., Utah State Univ., Logan, UT, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.245-62 (March 1983).
Reviews developments during the period 1979-82 in thermospheric chemistry and composition, thermal structure, energy sources and energy budget. The discussion is limited to middle and low latitudes. (195 refs.)

110748 Middle atmospheric electrodynamics. M.C.Kelley (School of Electrical Engng., Cornell Univ., Ithaca, NY, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.273-5 (March 1983).
Reviews of 1979-82 studies of the physics and chemistry of the Earth's middle atmosphere in general and in middle atmosphere electrodynamics in particular. New techniques which have been developed to study this region and several exciting and controversial results accruing from this effort are discussed. (34 refs.)

110749 Minor constituents in the stratosphere and mesosphere. S.Solomon (Aeronomy Lab., NOAA, Boulder, CO, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.276-83 (March 1983).
Presents a survey of research in the field of middle atmosphere chemistry from 1979 to 1982. The possiblity of anthropogenic perturbation to the stratospheric ozone layer, particularly as a result of chlorocarbons, remained a subject of interest, and has been studied with increasingly detailed models during this period. A great deal of data on the distributions of many important species have been obtained, leading to substantial progress in the understanding of the processes controlling the photochemistry of minor species in the middle atmosphere. (222 refs.)

110750 Middle atmosphere dynamics. D.L.Hartmann (Dept. of Atmospheric Sci., Univ. of Washington, Seattle, WA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.283-90 (March 1983).
Reviews efforts of scientists in the United States to understand the large-scale dynamics and climatology of the middle atmosphere, which have appeared in the literature between January 1979 and September 1982. The body of the

review is divided into six sections and followed by a final section suggesting a few of the areas where progress may be expected in the future. The six major subject headings are: (1) new phenomena; (2) large-scale waves and instabilities; (3) equatorial wave, mean-flow interaction—long-period oscillations; (4) extratropical wave,mean-flow interaction—sudden warmings; (5) climatology and general circulation of the middle atmosphere; and (6) transport of trace chemicals. 94.10Q Airglow and nightglow

110751 OH airglow phenomena during the 5-6 July 1982 total lunar eclipse. A.W.Peterson (Dept. of Phys. & Astron., Univ. of New Mexico, Albuquerque, NM, USA), G.W.Adams.
Appl. Opt. (USA), vol.22, no.17, p.2682-5 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
The first photographs of the OH airglow the authors took during a lunar eclipse revealed large (20-30 km) east-west waves from horizon to horizon which drifted northward at 10-15 m/sec. These waves were not typical of the ripples that have been found to be well-correlated with lower lunar transit. (7 refs.)

110752 Observations of optical emissions from precipitation of energetic neutral atoms and ions from the ring current. R.P.Rohrbaugh, B.A.Tinsley, H.Rassoul (Univ. of Texas, Austin, TX, USA), Y.Sahai, N.R.Teixeira, R.G.Tull, D.R.Doss, A.L.Cochran, W.D.Cochran, E.S.Barker.
J. Geophys. Res. (USA), vol.88, no.A8, p.6317-30 (1 Aug. 1983).
Observations of N_2^+ 1 N, H Balmer β(HB$a\beta$) and other emissions due to particle precipitation have been observed at two low-latitude sites (Mt. Haleakala, Hawaii, and Cachoeira Paulista, Brazil) and one mid-latitude site (McDonald Observatory, Southwest Texas). Results are compared for magnetic storms of April 13, 1981, and July 14, 1982. The emissions have the characteristics appropriate to the precipitation into the thermosphere of energetic neutral atoms and/or ions originating in the ring current. These characteristics include high rotational/vibrational excitation of the N_2^+ 1 N bands and at times the occurrence of HB$a\beta$ emission with the same onset time as the N_2^+ 1 N emission and partial correlation with it afterward. The latitude variation shows a strong increase from low to mid latitudes. The strongest emissions occur in the evening to midnight local time period, and the storm time variations shows strongest emissions during main phases. (36 refs.)

110753 Altitude profiles of OH and O_2 near infrared airglows in the evening twilight. T.Makino, H.Yamamoto, H.Sekiguchi (Dept. of Phys., Rikkyo Univ., Tokyo, Japan).
J. Geomagn. & Geoelectr. (Japan), vol.35, no.3, p.57-64 (1983).
The height distributions of the airglow emissions in the regions of 1.3 μm and 1.6 μm were observed by a rocket-borne radiometer 83 minutes after sunset at Uchinoura, Japan. The 1.6 μm emission from the lower vibrational levels of OH occurred in a wider height range and at a lower peak height by a few kilometers than the previous midnight profiles in the same wavelength region. The 1.3 μm emission, including the O_2 1.27 μm airglow and the OH airglow from higher vibrational levels, had a peak emission height at 90 km and a height width of 14 km. A possibility for a contribution of the HO_2 reaction to the formation of vibrationally excited OH is discussed in the light of the observed airglow profiles. (14 refs.)

PRESTO: a programmable etalon spectrometer for twilight observations .... See Entry 110665

Observations of large scale *F*-region irregularities using airglow emissions at 7774 Å and 6300 Å .... See Entry 110759

94.10S Aurora

110754 Auroral kilometric radiation induced by double layers. S.Bujarbarua (Inst. of Advanced Study in Sci. & Technol., Assam Sci. Society, Gauhati, India), M.Nambu.
J. Phys. Soc. Jpn. (Japan), vol.52, no.7, p.2285-8 (July 1983).
A new generation mechanism of the auroral kilometric radiation (AKR) is proposed. The induced bremsstrahlung interaction between the auroral electrons and the moving double layers is effective for the generation of the auroral kilometric radiation. The theory predicts the close correlation between the moving double layers and AKR. The model explains the fine structure of the AKR which is interpreted as the motion of the source region (double layers) down and up the magnetic field line at a velocity of about 10 km/sec.

110755 Power spectra analysis of auroral occurrence frequency. S.M.Silverman (Dept. of Phys., Boston Coll., Chestnut Hill, MA, USA), R.Shapiro.
J. Geophys. Res. (USA), vol.88, no.A8, p.6310-16 (1 Aug. 1983).
Power spectral analyses have been carried out on a data set of Swedish visual auroras for the period 1721 to 1943. Besides the anticipated 11-year, annual, and semiannual cycles, an unexpected peak near 1.4 years is found. The amplitude of this latter peak, while smaller than that of the 6-month and 12-month peaks, is statistically significant at between the 5% and 1% level and is found consistently in a sequence of spectra covering consecutive, overlapping, approximately 22-year data segments. The semiannual variation becomes extremely weak during the prolonged solar activity minimum at the beginning of the nineteenth century, and also shows some lessening during the prolonged solar activity minimum near the beginning of the twentieth century. The 1.4-year peak shows a strong modulation of about 65 to 68 years and an additional long-term trend of the order of centuries. The origin of this peak is unknown. (26 refs.)

110756 Generation of auroral arc elements in an inverted-V arc due to ion cyclotron turbulence. J.R.Kan (Geophys. Inst., Univ. of Alaska, Fairbanks, AK, USA).
J. Geophys. Res. (USA), vol.88, no.A8, p.6339-45 (1 Aug. 1983).
By using a two-dimensional particle simulation it is shown that the electrostatic ion cyclotron turbulence driven by the field-aligned current on auroral field lines can lead to striations of the current into east-west aligned current sheets of ion gyroradius scale ($L_a \sim \rho_i$). Physical mechanism of the striation can be identified with nonlinear mode couplings of ion cyclotron waves resulting in condensation of the wave energy into a zero-frequency mode. It is proposed that the auroral arc elements ($L_a \sim \rho_i$), which collectively give rise to the inverted-V arc ($L_v \gg \rho_i$), can be produced by the east-west aligned striations of the field-aligned current on inverted-V field lines. (30 refs.)

110757 US contributions to auroral aeronomy, 1979-1982. M.H.Rees (Geophys. Inst., Univ. of Alaska, Fairbanks, AK, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.241-5 (March 1983).
Reviews UV spectra, visible and near IR observations of the polar dayside cusp, atomic and molecular physics related to auroral studies, energetic particle transport, modelling, and X-ray imaging. (82 refs.)

A new radar auroral backscatter experiment .... See Entry 110782

94.20 PHYSICS OF THE IONOSPHERE

(for planets, see 96.30)

110758 Short wavelength gradient-drift waves at high latitudes. K.Schlegel, J.-P.St-Maurice (Max-Planck-Inst. fur Aeronomie, Katlenburg-Lindau, Germany).
Ann. Geophys. (France), vol.1, no.3, p.259-64 (May-June 1983).
The Farley-Buneman instability can easily excite irregularities as small as 15 cm in size at high latitudes. When these waves grow in amplitude they in turn generate irregularities of similar scale sizes. These secondary waves are strongly affected by the density gradients of the primary waves. The authors therefore discuss the behavior of these secondary gradient-drift waves within the framework of a kinetic theory, taking finite Larmor-radius effects and Debye-length effects into account. The solution is compared to existing fluid expressions. The dispersion relation is discussed in terms of some of the parameters which determine its solution. Growth rates and wave frequency curves are calculated. The waves with **k** components parallel to the magnetic field are studied. (16 refs.)

110759 Observations of large scale *F*-region irregularities using airglow emissions at 7774 Å and 6300 Å. Y.Sahai, J.A.Bittencourt, N.R.Teixeira, H.Takahashi (Inst. de Pesquisas Espaciais, Conselho Nacional de Desenvolvimento Cientifico e Tecnologico, Sao Paulo, Brazil).
Ann. Geophys. (France), vol.1, no.3, p.271-6 (May-June 1983).
Simultaneous scanning measurements of the atomic oxgyen 7774 Å and 6300 Å emissions, to study the dynamics of low-latitude large scale *F*-region irregularities, were carried out at Cachoeira Paulista (geographic coordinates 22.7°S, 45.0°W; geomagnetic latitude 11.95°S), Brazil, during the period October-November, 1980. The measurements were made with a two-channel photometer which permitted scanning observations both along and across the magnetic meridian. Observations at 7774 Å can detect large scale irregularities near the *F*-region peak height, whereas observations at 6300 Å detect such irregularities at an altitude about 50 km to 100 km lower, depending on the *F*-region height. On many nights, during spread-*F* conditions the presence of large intensity depletions of short duration were detected in both emissions. These depletions were observed to move towards the east in the east-west scans, and apparently towards the south in the north-south scans. Salient features of these observations are presented and discussed. (23 refs.)

110760 Studies on ionospheric scintillations recorded at Nagpur. M.S.Korde, G.N.Navaneeth (Dept. of Phys., Nagpur Univ., Nagpur, India).
Indian J. Radio & Space Phys., vol.12, no.2, p.33-6 (April 1983).
Ionospheric scintillations of 136 MHz plane polarized signals from the geostationary satellite ETS-II were observed at Nagpur, a low latitude station, during the period 1980-81. The onset time of scintillation was found to be predominantly around 1930 hrs LT. This has been explained in terms of sunset at the mean field height of the ionosphere. The diurnal and seasonal variation of scintillation activity has been analyzed. (13 refs.)

110761 Correlation between observed VLF phase deviation and solar X-ray flux during solar flares. P.Pant, H.S.Mahra, M.C.Pande (Uttar Pradesh State Obs., Naimi Tal, India).
Indian J. Radio & Space Phys., vol.12, no.2, p.40-2 (April 1983).
Correlation between the observed phase deviation of GBR 16 kHz VLF signals and the solar X-ray flux in the bands 0.5-4 and 1-8 Å during solar flare events has been studied. It is found that the unnormalized phase deviation show a better correlation with the observed X-ray flux than the correlation with the normalized phase deviations. The threshold X-ray flux to produce a detectable sudden phase anomaly has been estimated. (5 refs.)

110762 Dependence of frequency power law exponent of ionsopheric radiowave absorption on solar zenith angle. R.Chandrasekhar, P.Victor, D.I.Devi, D.N.M.Rao, T.S.N.Somayaji, K.V.V.Ramana (Dept. of Phys. , Andhra Univ., Waltair, India).
Indian J. Radio & Space Phys., vol.12, no.2, p.43-6 (April 1983).
A study of the effect of the solar zenith angle on the frequency power law exponent derived from simultaneous vertical incidence multifrequency ionospheric absorption measurements available from a number of low and midlatitude stations has shown that the exponent increases when deviative absorption becomes relatively more significant compared to non-deviative absorption. A numerical simulation using a double α-Chapman type absorbing zone yielded results identical to the experimental observations. (7 refs.)

110763 Effect of travelling ionospheric disturbances on HF phase-path measurements. K.N.Iyer (Dept. of Phys., Saurashtra Univ., Raijkot, India).
Indian J. Radio & Space Phys., vol.12, no.2, p.47-9 (April 1983).
The signature of travelling ionospheric disturbances on the phase-path measurements of obliquely propagating HF signals is theoretically computed using a model for a travelling wave disturbance along the calculated ray path. The phase-path at a single frequency and the differential phase-path between two frequencies are found to have periodic fluctuations, not necessarily of the

same period as that of the causative travelling disturbance. The results could be applied to the interpretation of frequency fluctuations of standard time transmissions. (7 refs.)

110764 Abnormal quiet days and the effect of geomagnetic activity on the diurnal variation of equatorial geomagnetic field. J.H.Sastri (Indian Inst. of Astrophys., Bangalore, India).
Indian J. Radio & Space Phys., vol.12, no.2, p.53-5 (April 1983).
It is shown that a conspicuous noontime positive deviation in the asymmetric component of the *H* field at equatorial electrojet stations, associated with the solar wind on quiet days with $A_p \sim 5$, is not manifest if 'abnormal quiet days' and hence the influence of counter-electrojet conditions associated with them are taken into consideration. It is pointed out that the noontime positive swing of the asymmetric component in the *H* field on quiet days with $A_p \sim 5$ at electrojet stations is primarily due to changes in the local ionospheric dynamo region rather than in the solar wind. (12 refs.)

110765 Ionospheric plasma bubble encounters or *F* region bottomside traversals?. R.F.Benson (Lab. for Planetary Atmospheres, NASA/Goddard Space Flight Center, Greenbelt, MD, USA), H.C.Brinton.
J. Geophys. Res. (USA), vol.88, no.A8, p.6243-52 (1 Aug. 1983).
In situ AE-C and AE-E ion composition measurements, together with Manila and Huancayo ionosonde electron density profiles, are used in an attempt to distinguish between spacecraft encounters with equatorial plasma bubbles which have been pinched off from below, those still in the formation stage, and spacecraft excursions below the steep ionization gradient at the bottom edge of the postsunset *F* layer. Such excursions can result from quasi-periodic oscillations of the altitude of the *F* layer—as deduced from the ion composition measurements during the circular orbit phase of the low-inclination satellite AE-E. These results have important theoretical implications in that they are consistent with placing the bubble generation region on the steep density gradient of the lower ledge of the *F* region where O^+ is the dominant ion. (61 refs.)

110766 A comparative study of VHF scintillation and spread *F* events over Natal and Fortaleza in Brazil. R.T.de Medeiros, M.A.Abdu, I.J.Kanto (Inst. de Pesquisas Espaciais, Conselho Nacional de Desenvolvimento Cientifico e Tecnologico, Sao Paulo, Brazil).
J. Geophys. Res. (USA), vol.88, no.A8, p.6253-8 (1 Aug. 1983).
A comparative study is carried out of the equatorial ionospheric irregularity occurrences, as observed by range spread *F* events over Fortaleza and satellite VHF signal scintillation event over Natal for a one-year period 1978. Close association is observed in the occurrences and the durations of the irregularities at the two stations. Marked diffrences in the seasonal behavior of the occurrences of the irregularity events over these two stations are noted with respect to that over Huancayo, most important of them being while the latter station presents equinoctial maxima in the occurrence rates the Brazilian station shows an additional December peak. This result is explained as possible evidence of magnetic declineation control of the spread *F* irregularity generation and its seasonal dependence. (26 refs.)

110767 Polarization electric fields in the nighttime F layer at Arecibo. R.G.Burnside, J.C.G.Walker (Dept. of Atmospheric & Oceanic Sci., Univ. of Michigan, Ann Arbor, MI, USA), R.A.Behnke, C.A.Gonzales.
J. Geophys. Res. (USA), vol.88, no.A8, p.6259-66 (1 Aug. 1983).
Incoherent scatter radar measurements made in 1981 and 1982 are used to determine the electrical conductivity of the nighttime E and F regions at Arecibo, Puerto Rico. The height-integrated Pedersen conductivity of the F region extends that of the E region by a factor of 10 on the average. The authors conclude that, for the solar maximum conditions they have studied, the local E region has little influence on nighttime F region electrodynamics. Simultaneous measurements of ion and neutral velocities are often inconsistent with the hypothesis that a fully developed electric polarization field is generated by dynamo action in the local F region. A better explanation of these results is obtained by including the influence of polarization fields that originate in the F region of the conjugate hemisphere. (31 refs.)

110768 The Joule heat production rate and the particle energy injection rate as a function of the geomagnetic indices AE and AL. B.-H.Ahn, S.-I.Akasofu (Geophys. Inst., Univ. of Alaska, Fairbanks, AK, USA), Y.Kamide.
J. Geophys. Res. (USA), vol.88, no.A8, p.6275-87 (1 Aug. 1983).
As a part of the joint efforts of operating six meridian chains of magnetometers during the IMS, magnetic records from 71 stations are used to deduce the distribution of electric fields and currents in the polar ionosphere for March 17, 18, and 19, 1978. As a continuation of this project, the authors have constructed hourly distribution maps of the Joule heat production rate, the particle energy injection rate and their sum over the entire polar region on the three days. For this purpose the conductivity distribution is inferred at each instant partially on the basis of an empirical method devised by Ahn et al. (1982). The particle energy injection rate is estimated similarly by using an empirical method. The data set thus obtained allows estimation of the global Joule heat production rate U_J, the global particle energy injection rate U_A and the sum U_I of the two quantities. It is found that the three global quantities (watt) are related almost linearly to the AE(nT) and AL(nT) indices. (24 refs.)

110769 Inelastic scattering effects on photoelectron spectra and ionospheric electron temperature. K.Stamnes, M.H.Rees (Geophys. Inst., Univ. of Alaska, Fairbanks, AK, USA).
J. Geophys. Res. (USA), vol.88, no.A8, p.6031-9 (1 Aug. 1983).
Three sets of inelastic scattering cross sections have been used by various investigators in energy degradation computations of photoelectrons. The effects of the three sets upon photoelectron spectra in the ionosphere, electron heating rates and temperature, and dayglow emissions are examined for solar minimum and solar maximum conditions. Comparison of individual cross sections shows large differences among the three sets, but the overall inelastic scattering, summed over states and species, is sufficiently similar such that the effects on the electron heating rate and temperature is only minor. Photoelectron spectra differ in details at energies below about 20 eV. The major difference is found in the excitation and emission rates of some features in the dayglow spectrum. (33 refs.)

110770 Production of auroral zone *E* region irregularities by powerful HF heating. F.H.Hibberd, E.Nielsen, P.Stubbe, H.Kopka, M.T.Rietveld (Max-Planck-Inst. fur Aeronomie, Katlenburg-Lindau, Germany).
J. Geophys. Res. (USA), vol.88, no.A8, p.6347-51 (1 Aug. 1983).
Production of ionospheric 1-m irregularities in the auroral zone *E* region by high power ionospheric heating has been observed by means of the STARE auroral radar. Irregularities were produced at night, on eight occasions, by using an *O* mode heating wave and on two occasions by using an *X* mode heating wave. The growth time of the irregularities is found to be approximately 30 s. Several physical possibilities to explain these findings are discussed, and a mechanism is suggested that is closely related to Sato's mechanism of quiet auroral arc formation. (15 refs.)

110771 Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979.
J. Atmos. & Terr. Phys. (GB), vol.45, no.7 (July 1983).
Conference held at: Toronto, Ont., Canada. Date May 1980. The following topics were dealt with: solar eclipse of 26 February 1979, electron density, particle precipitation, lower ionosphere, Red Lake, Canada, E-region, NO, ion composition, D-region, O, O_2 OH, mobility, electrical parameters and differential Doppler measurements.

110772 Electron density and energetic particle precipitation observed during the eclipse of 26 February 1979. L.G.Smith, M.K.McInerney, H.D.Voss (Dept. of Electrical Engng., Univ. of Illinois, Urbana, IL, USA).
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.427-36 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
Electron density profiles and energetic particle fluxes are determined from two rockets launched, respectively, at the beginning and end of totality during the solar eclipse of 26 February 1979. These, and one other rocket at the same time of day on 24 February 1979, were launched from a temporary site near Red Lake, Ontario. The electron density profile from 24 February 1979 shows the electron density to be normal above 110 km, to rocket apogee. Below 110 km the electron density is enhanced, by an order of magnitude in the *D*-region, compared with data from Wallops Island at the same solar zenith angle. The enhancement is qualitatively explained. During totality, on 26 February 1979, the electron density above 100 km to rocket apogee is reduced by a factor of about three, as seen in other eclipses. Below 110 km, however, the electron density is much greater than observed during previous eclipses. The particle flux measured on the 26 February was an order of magnitude less than that on the 24 February but showed greater variability. (20 refs.)

110773 A model of the lower ionosphere above Red Lake, Canada, during the 26 February 1979 solar eclipse. R.D.Harris, L.C.Howlett, K.D.Baker (Space Measurements Lab., Utah State Univ., Logan, UT, USA).
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.437-50 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
Measurements of ionization sources, ionization profiles and minor atmospheric constituents were conducted during the 26 February 1979 solar eclipse above Red Lake, Canada. A model of the lower thermosphere is developed to describe the *D*- and *E*-regions of the ionosphere for this case with the model being guided by the measurements. During the eclipse a rather intense particle precipitation event was in progress. For this reason an auroral deposition code is coupled to a chemical-kinetics code to calculate degraded primary and secondary electron fluxes, ionization rates, positive ion and electron densities. The model is calibrated with the experimental measurements of electron flux below 100 km and electron density between 70 and 150 km. (25 refs.)

110774 Satellite observations of energetic electron precipitation during the 1979 solar eclipse and comparisons with rocket measurements. E.E.Gaines, W.L.Imhof, H.D.Voss, J.B.Reagan (Lockheed Palo Alto Res. Lab., Palo Alto, CA, USA).
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.451-5 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
During the solar eclipse of 26 February 1979, the P78-1 satellite passed near Red Lake, Ontario, at an altitude of ~600 km. On two consecutive orbits spanning the time of total eclipse, energetic electrons were measured with two silicon solid state detector spectrometers having excellent energy and angular resolution. Significant fluxes of precipitating electrons were observed near the path of totality. Comparisons of flux intensities and energy spectra with those measured from a Nike Orion and two Nike Tomahawk rockets launched near Red Lake before and during total eclipse give good agreement and indicate that the electron precipitation was relatively uniform for more than an hour and over a broad geographical area. (3 refs.)

110775 *E*-region nitric oxide concentrations inferred from the 26 February 1979 eclipse expedition. W.Swider, R.S.Narcisi (Air Force Geophys. Labs., Hanscom Air Force Base, MA, USA).
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.457-60 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
Nitric oxide (NO) concentrations are determined from the analysis of positive ion composition data obtained by AFGL for eclipse and post-eclipse conditions near Red Lake, Canada. Values of about 3×10^8 cm^{-3} for 105-110 km and about 3×10^7 cm^{-3} for 90 km have been established. A residual ion-pair production rate of about 50 cm^{-3} s^{-1} is estimated for eclipse totality at 110 km. A factor of two uncertainty is thought to be appropriate for all deduced values. The calculated NO concentrations appear be within the range of typical variations for this reason (late winter) and latitude (51°N). (11 refs.)

110776 Positive and negative ion composition measurements in the *D*-and *E*-regions during the 26 February 1979 solar eclipse. R.Narcisi, A.Bailey, G.Federico, L.Wlodyka (Air Force Geophys. Lab., Hanscom Air Force Base, MA, USA).
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.461-78 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
Two rockets bearing quadrupole mass spectrometers capable of measuring both positive and negative ion composition were launched from Red Lake, Canada, during the solar eclipse. Both instruments had liquid helium cryopumps and shock-attaching conical samplers. The payloads also contained two Gerdien condensers to measure total positive and negative ion concentrations and ion mobilities. Altitude control systems aligned the payloads with the velocity vector throughout ascent and descent. The positive ion composition, ionization, and negative ion distributions are discussed. Comparisons are made with prior negative ion measurements during similar daytime auroral zone absorption (AZA) events. Some characteristics of the precipitating particles are found from these and past observations in daytime AZA events. (14 refs.)

110777 Steady-state model of the *D*-region during the February 1979 eclipse. W.Swider, R.S.Narcisi (Air Force Geophys. Lab., Hanscom Air Force Base, MA, USA).
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.493-8 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
Significant electron precipitation of sufficiently stable duration permits the use of a steady-state model for the description of the charged particle distributions in the *D*-region during the eclipse of 26 February 1979. For the positive ions, thc current results support conclusions reached in conjunction with the SPE-disturbed *D*-region of November 1969. Again, the three-body process leading to the clustering of NO^+ with CO_2 is determined to be the principal loss mechanism for NO^+ ions below 80 km. Inexplicably, the loss of NO^+ by clustering with N_2 is only of equal importance, at most. Carbon

dioxide apparently is an important agent in hastening the formation of the heavier oxonium ions, $H_7O_3^+$ and $H_9O_4^+$. (29 refs.)

110778 *D*-region positive and negative ion concentration and mobilities during the February 1979 eclipse. T.D.Conley (Air Force Geophys. Lab., Hanscom Air Force Base, MA, USA), E.R.Hegblom, R.S.Narcisi.
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.499-513 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
Positive and negative ion concentrations and mobilities are obtained from an analysis of Gerdien condenser measurements on rocket flights, A10.802-1 and A10.802-2, during and after eclipse totality. The aerodynamic instrument calibration and the data analysis techniques are discussed. The concentrations at very low altitudes suggest that a relativistic electron precipitation event was occurring during the measurements. The ion concentration measurements along with electron density measurements made by other groups during the eclipse are used to calculate the negative ion: electron ratio, and the lumped parameter detachment rate. These results are compared with prior measurements during eclipse and solar proton events and code results are determined. (38 refs.)

110779 Differential Doppler measurements of the ionosphere during a solar eclipse. J.R.Clynch, D.S.Coco, B.A.Renfro (Appl. Res. Labs., Univ. of Texas, Austin, TX, USA).
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.527-35 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
The effects of the solar eclipse of 26 February 1979 on the ionosphere were measured using differential Doppler techniques. Navy navigation satellite passes were monitored at 12 sites located across the North American continent. These yield a measurement of the vertical columnar electron content along a north-south line. Different sites monitoring the same pass provide simultaneous observations of ionospheric variations along different longitude lines. Two satellite passes occurred during or just after the eclipse. These data show a shoulder just northward of the umbra region and a trough just behind the umbra containing large horizontal gradients. This sharp trough recovered quickly with a half-life of about 10 min. (3 refs.)

110780 Effects of total solar eclipse of 16th February 1980 on the HF communications in India. R.Sethuraman (Dept. of Electronics, Anna Univ., Madras, India), M.Mukunda Rao, C.Ravichandran.
J. Inst. Electron. & Telecommun. Eng. (India), vol.29, no.3, p.127-8 (March 1983). [received: Aug. 1983]
Measurements of field strength and fading observed on HF communication links Bombay-Madras and Nagpur-Madras on 13406 kHz and 9067 kHz respectively during the total solar eclipse of 16th February 1980 are presented. The observed behaviour at these two frequencies is explained in terms of absorption and fading. Field strengths on short waves record an increase during the eclipse. Marked increase in fading which is probably due to bending of the ionosphere at the time of totality is discussed. (9 refs.)

110781 foF2 response to IMF sector-boundary crossings. L.Triskova (Geophys. Inst., Czechoslovak Acad. of Sci., Praha, Czechoslovakia).
J. Geophys. (Germany), vol.53, no.1, p.68-71 (1983).
An analysis of night-time critical F2-layer frequencies in the equinoctial period of the 19th, 20th and 21st solar cycles has shown that the F2-layer response to sector-boundary crossings represents a response to the change of geomagnetic activity caused by the change of IMF polarity. For boundary crossings of the $+/-$ type, the critical frequencies in both hemispheres in general decrease in March and April, and increase in September and October while the reverse holds for $-/+$ crossings. (16 refs.)

110782 A new radar auroral backscatter experiment. E.Nielsen, W.Guttler (Max-Planck-Inst. fur Aeronomie, Katlenburg-Lindau, Germany), E.C.Thomas, C.P.Stewart, T.B.Jones, A.Hedberg.
Nature (GB), vol.304, no.5928, p.712-14 (25 Aug. 1983).
In 1982 a new radar auroral backscatter system, SABRE (Sweden and Britain Radar Experiment), commenced operation in northern Europe. Observations with this ground-based system allow estimates to be made of the electric fields in the auroral E-region. As an electric field probe, the coherent radar technique is unique in that measurements are made over a large area (~ 200000 km^2) with good spatial resolution (20×20 km^2) and with a temporal resolution of typically 20 s. The system field of view covers an *L*-value range 4.3-5.8. Observations of two pulsation events are presented. (19 refs.)

110783 Analytic solution for the two-frequency mutual coherence function for spherical wave propagation. D.L.Knepp (Mission Res. Corp., Santa Barbara, CA, USA).
Radio Sci. (USA), vol.18, no.4, p.535-49 (July-Aug. 1983).
The quadratic approximation for the phase structure function is used to obtain the two-frequency mutual coherence function for spherical wave propagation through a finite slab with transmitter and receiver located in free space on opposite sides of the slab. General analytic solutions are derived for two cases. In the first case the random slab is represented by a one-dimensional power spectrum of electron density fluctuations corresponding to propagation through elongated irregularities as would occur for an equatorial satellite link corresponding to propagation through elongated irregularities as would occur for an equatorial satellite link to a ground station. In the second case the random slab consists of isotropic ionization irregularities. Both cases taken together represent the extremes of the range of results to be expected for propagation through ionospheric fluctuations, solar wind irregularities, or ionization irregularities caused by barium cloud instabilities. (22 refs.)

110784 Ionospheric scintillations. D.M.Wu, N.Marcuvitz (Microwave Res. Inst., Polytech. Inst. of New York, Farmingdale, NY, USA).
Radio Sci. (USA), vol.18, no.4, p.589-607 (July-Aug. 1983).
A renormalization technique is applied to the problem of ionospheric scintillations. In the forward scattering limit, using a Markov approximation for ionospheric fluctuations and renormalized moment equations, the wave statistics for a plane or beam propagating through the ionosphere are derived. An experimental power spectrum, obtained from in situ measurements by the Explorer E satellite and corresponding to electron density fluctuations of 20%, is used to calculate the scintillation index S_4 for nighttime equatorial scintillations. (38 refs.)

110785 First bistatic oblique-incidence ionograms between digital ionosondes. J.W.Wright (Environmental Res. Lab., NOAA, Boulder, CO, USA), R.I.Kressman.
Radio Sci. (USA), vol.18, no.4, p.608-14 (July-Aug. 1983).
Identical digital ionosondes (dynasondes) at Brighton, Colorado and at White Sands Missile Range, New Mexico, 864 km distant, were synchronized for bistatic sounding in multifrequency and fixed frequency recording patterns. Three propagation modes are observed, identified, and reconciled with standard propagation theory; these include one-hop propagation by sporadic *E* (Es) and the *F*-region and two-hop (F-Es). The results encourage the concept of a global real time ionospheric monitoring network consisting of about 90 instruments that perform vertically incident and coordinated bistatic soundings, to yield a total of about 320 measurement 'locations'. (11 refs.)

110786 Development of a minicomputer atmospheric noise model. D.B.Sailors, R.P.Brown (Ocean & Atmospheric Sci. Div., Naval Ocean Systems Center, San Diego, CA, USA).
Radio Sci. (USA), vol.18, no.4, p.625-37 (July-Aug. 1983).
A practical but simplified atmospheric noise model in universal time for 1-MHz F_{am} usable in estimating system signal-to-noise ratios in microminicomputer-based HF propagation prediction systems is presented. Numerical mapping techniques were used to represent worldwide atmospheric noise in 24 numerical maps: one for each of six 4-hour UT time blocks and each of four 3-month periods. This representation results in a minimum reduction by one fifth in the number of coefficients necessary in computer memory over that of an earlier model in which the map represented an entire 24-hour day. (15 refs.)

110787 Variation of the inhomogeneity spectrum of the electron concentration in the lower ionosphere under the influence of powerful electromagnetic radiation. G.M.Teptin, Yu.M.Stenin (Kazan' State Univ., Kazan, USSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.11, p.886-90 (Nov. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.11, p.1244-8 (Nov. 1982). [received: Sept. 1983]
The variation of the spectrum of turbulent fluctuations in the electron concentration in the lower ionosphere under the influence of powerful electromagnetic radiation is considered. It is shown that under specified conditions the influence of powerful electromagnetic radiation on the region of effective scattering of radio waves can lead both to attenuation and amplification of the useful signal level. (10 refs.)

110788 Scattering of escaping electrons by helicon oscillations in a weakly magnetized plasma. V.B.Krasovitskii, V.G.Razdorskii (Sci.-Res. Inst. of Phys., Rostov-on-Don State Univ., Rostov, USSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.11, p.890-5 (Nov. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.11, p.1249-54 (Nov. 1982). [received: Sept. 1983]
The effect of escaping electrons in an ionospheric plasma in parallel electric and magnetic fields is discussed. It is shown that the driving of helicon oscillations under the conditions of cyclotron resonance is accompanied by elastic scattering of fast resonant particles by waves and by the isotropization of the distribution function of the escaping electrons and the development of a flux in velocity space. It is made clear that when a source of slow electrons is present there exists in the plasma a steady dynamic regime which is characterized by a steady-state spectrum of helicon turbulence. The spectrum of the oscillations and the flux of escaping electrons scattered transversely to the magnetic field are found. (14 refs.)

110789 The method of multiply reflected waves in the problem of the propagation of electromagnetic waves in regular waveguides. G.I.Makarov, L.A.Fedorova (Leningrad State Univ., Leningrad, USSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.12, p.977-96 (Dec. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.12, p.1384-409 (Dec. 1982). [received: Sept. 1983]
Various aspects of the discontinuity method are discussed which touch mainly on the theory of propagation of long and ultralong waves in an isotropic Earth-ionosphere waveguide channel. The article consists of three parts and an Appendix. In the first part the exact representations of the field are analyzed in detail: in the form of a sum of contour integrals, in the form of a modified (double infinite) series of zonal harmonics, and in the form of an expansion in plane waves. In the second part of this paper approximate representations of the field are discussed which are associated with the method of path integrals, the geometrooptical approximation of multiply reflected waves, and finally their quasigeometrooptical approximation, including the diffraction corrections of Wait. In the third part the application of the rigorous approach to the problem of representation of the field in a waveguide in the form of a series of multiply reflected waves is illustrated by the example of two model problems. Finally, a review of the papers devoted to the development and certain applications of the discontinuity method is given in the Appendix. Individual examples from acoustics, quasioptics, and mathematical physics, as well as from the theory of propagation of short radio waves around the Earth, are also given. (76 refs.)

110790 Ionospheric electrodynamics and irregularities: a review of contributions by US scientists from 1979 to 1982. A.D.Richmond (Space Environment Lab., NOAA, Boulder, CO, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.234-41 (March 1983).
Global-scale electrodynamic phenomena are considered separately, with the greater weight of the report going to global phenomena. (230 refs.)

110791 Polar and auroral phenomena: a review of US progress during 1979-1982. P.H.Reiff (Dept. of Space Phys. & Astron., Rice Univ., Houston, TX, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.418-33 (March 1983).
The quadrennium 1979-82 has been a highly active time in the field of polar and auroral research, with nearly 400 research papers and thirty general or topical review papers written by US authors. The author highlights progress in understanding auroral morphology, precipitating particle fluxes, the spectra and sources of upward-flowing particles, large-scale Birkeland currents, and theoretical and experimental advances in auroral-scale electrodynamics. (382 refs.)

110792 New tools for magnetospheric research. R.A.Greenwald (Appl. Phys. Lab., Johns Hopkins Univ., Laurel, MD, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.434-49 (March 1983).
Examines some of the new techniques that are being used to increase our understanding of the Earth's magnetosphere and the manner in which it couples to the high latitude ionosphere. Particular attention is devoted to experiments in which one attempts to modify the environment in the magnetosphere and high latitude ionosphere, and to the increased usage of incoherent and coherent scatter radars for high latitude studies of magnetosphere-ionosphere coupling. The author notes the trend toward developing constellations of satellites and ground-based instrumentation in order to obtain a better understanding of the global nature of magnetosphere-ionosphere coupling and the increased use of large computer-based suites of geophysical data. 94.30 PHYSICS OF THE MAGNETOSPHERE

(for planets, see 96.30)

110793 Identification of electromagnetic sources. F.Glangeaud, C.Latombe (ENSIEG, Saint-Martin-d'Heres, France).
Ann. Geophys. (France), vol.1, no.3, p.245-51 (May-June 1983).
Describes a study of natural electromagnetic waves generated in the magnetosphere by a wave-particle interaction process and presents results which identify two sources using six component signals. The authors identification needs all the information of the spectral matrix, especially its eigenvalues and eigenvectors. This spectral matrix is computed with classical Fourier methods. The authors see the property that the rank of the spectral matrix or the number of non-zero eigenvalues indicates the number of sources. As the eigenvalues are estimated a criterion to separate the significant eigenvalues is proposed. As it is known that there are two sources, the authors show that the identification of the sources is not possible without an hypothesis on the properties of the medium through which the waves propagate. With a rather realistic one it is possible to identify the two sources of Pc 1. (9 refs.)

110794 Bias for spectral density estimates of electromagnetic wave field components in a magnetoplasma. F.Lefeuvre, D.Lagoutte (Lab. de Phys. et Chimie de l'Environnement, Orleans, France).
Ann. Geophys. (France), vol.1, no.3, p.265-70 (May-June 1983).
The auto- and cross-power spectral densities of the electric and magnetic components of an electromagnetic wave field propagating in a magnetoplasma can be related to a wave distribution function (WDF) that specifies how the wave energy density is distributed with respect to the wave-number vector **K**. Those relations are used to evaluate the bias errors of the power spectral density estimates of the field components. As an application the WDF is assumed to be constant over the frequency band of analysis and the waves are supposed to propagate in the whistler mode. Under these hypotheses the power spectral densities of the magnetic components are unbiased while the power spectral densities of the electric components are systematically biased. (11 refs.)

110795 Geomagnetic implications of a simple IMF model. U.Villante, P.Francia, M.Vellante (Istituto di Fisica, Univ. di L'Aquila, L'Aquila, Italy).
Ann. Geophys. (France), vol.1, no.3, p.277-82 (May-June 1983).
Assuming that the strength of the interaction between the solar wind and the Earth's magnetosphere is only determined by the amount of the southward component of the interplanetary magnetic field as observed in a magnetospheric coordinate system (Russel and McPherron, 1973). The authors evaluated the geomagnetic consequences of a tilted current sheet corotating with the Sun. In addition to the semi-annual variation, the current sheet rotation may lead to the appearance, in the power spectra of the geomagnetic indices, of doublet structures with periods close to T_s and $T_s/2$, T_s being the period of the solar rotation as seen from Earth. The long term evolution of the geomagnetic activity may be related to the long term evolution of the current sheet orientation. (30 refs.)

110796 Effect of solar flare on the field intensity of VLF atmospherics. A.B.Bhattacharya, R.Bhattacharya (Dept. of Phys., Serampore Coll., Serampore, India).
Indian J. Radio & Space Phys., vol.12, no.2, p.56-8 (April 1983).
Observations of the integrated field intensity of VLF atmospherics reveal some interesting features due to their association with the ionospheric effects of a solar flare. The results obtained from an analysis of the observations from Oct. 1976 to Sep. 1979 are reported with an emphasis on the occurrences, time delay, duration and the magnitude. (4 refs.)

110797 Similarity in the characteristics of sweepers and VLF emissions. S.K.Trehan, S.Sekhar Dey, A.K.Sen.
Indian J. Radio & Space Phys., vol.12, no.2, p.62-3 (April 1983).
Sweepers have been observed to occur at random throughout the day and night and show a seasonal dependence on both amplitude and rate of occurrence. A close examination of the phenomena shows a great resemblance with the characteristics of VLF emissions. (7 refs.)

110798 Evolution of ion distributions across the nearly perpendicular bow shock: specularly and nonspecularly reflected-gyrating ions. N.Sckopke, G.Paschmann (Max-Planck-Inst. for Phys. und Astrophys., Garching, Germany), S.J.Bame, J.T.Gosling, C.T.Russell.
J. Geophys. Res. (USA), vol.88, no.A8, p.6121-36 (1 Aug. 1983).
Ion velocity space distributions measured with Los Alamos/Garching instruments on ISEE 1 and 2 across the Earth's bow shock have revealed that the nearly perpendicular shock reflects some fraction of the incident solar wind ions over a wide range of Mach numbers. The relative density of the reflected ions varies from 1-3% of the solar wind density at $M_A \approx 2$ to 15-25% at $M_A = 8$-12, in qualitative agreement with computer simulations and with predictions that indicate that such ions are needed to provide essential dissipation at the shock. These ions gyrate about **B** in the plasma rest frame with a speed of $\sim 2\, v_{in}$, where v_{in} is the normal component of the solar wind flow, and their density increases by ~2 orders of magnitude at the forward end of the 'foot' of the shock profile ~0.7 ion gyroradii upstream from the shock ramp. This is substantial evidence that the bulk of these ions have been reflected at the shock in a nearly specular fashion. Evidence also exists that a much smaller fraction is reflected nonspecularly. (35 refs.)

110799 Ray-tracing studies and path-integrated gains of ELF unducted whistler mode waves in the Earth's magnetosphere. C.Y.Huang, C.K.Goertz (Dept. of Phys. & Astron., Univ. of Iowa, Iowa City, IA, USA).
J. Geophys. Res. (USA), vol.88, no.A8, p.6181-7 (1 Aug. 1983).
Gyroresonance and Landau resonance interactions between unducted low-frequency whistler waves and trapped electrons in the Earth's plasmasphere have been studied. Ray paths for waves launched near the plasmapause have been traced. In agreement with findings by Thorne et al. (1979), the authors have found waves which return through the equatorial zone with field-aligned wave normal angles. However, when the growth along the ray path is calculated for such waves, assuming an electron distribution function of the form $E^{-n} \sin^m \alpha$, it is found that for all the waves considered, the local growth rate becomes negative before plasmapause reflection, limiting the total gain to small values. Most waves reach zero gain before reflection. This is the result of Landau damping at oblique propagation angles, which necessarily occurs before reflection can take place. It is concluded that the concept of cyclic ray paths does not provide an explanation for the generation of unguided plasmaspheric hiss. (21 refs.)

110800 Observational evidence of Z and L-O mode waves as the origin of auroral kilometric radiation from the Jikiken (EXOS-B) satellite. H.Oya, A.Morioka (Geophys. Inst., Tohoku Univ., Sendai, Japan).
J. Geophys. Res. (USA), vol.88, no.A8, p.6189-203 (1 Aug. 1983).
The Jikiken satellite, which had an initial pedigree and apogee of 250 km and 30050 km, respectively, and an orbit inclination of $-31°$, passed through critical regions where auroral kilometric radiation (AKR) spectra were obtained on at least five occasions during a period from January 31, 1979, to June 21, 1980. On all of these occasions the AKR spectra revealed cutoff phenomena at the local Z cutoff frequency, indicating a continuation of the spectra from the high-frequency side down to the Z mode wave frequency range and crossing over the local X cutoff frequency rather than being cut off at that frequency. Thus when observations were made near the low-latitude portion of the source region, the AKR waves generate spectra that continuously cover the frequency range corresponding to Z mode and L-O mode waves. The authors argue that the most plausible mechanism that gives a consistent interpretation of this spectral characteristic is the mode conversion theory. In other words, the plasma waves that are generated in the hybrid mode in the source regions are converted into Z mode waves that propagate toward dense plasma regions where the wave frequency coincides with the local plasma frequency and where a part of their energy is transferred to waves of the L-O mode that can escape toward outer space. (51 refs.)

110801 Type IPDP magnetic pulsations and the development of their sources. T.Pikkarainen, J.Kangas (Dept. of Phys., Univ. of Oulu, Oulu, Finland), B.Kiselev, N.Maltseva, R.Rakhmatulin, S.Solovjev.
J. Geophys. Res. (USA), vol.88, no.A8, p.6204-12 (1 Aug. 1983).
Intervals of pulsations of diminishing periods (IPDP) magnetic pulsations data have been analyzed from several recording campaigns and from stations that are widely spaced in both meridional and azimuthal directions. On the basis of their local time occurrence it seems useful to divide the events into at lest two main categories: $1400<\mathrm{LT}<1800$ and $1800<\mathrm{LT}<2400$. Those events which are not only observed at auroral latitudes typically develop slowly and extend at the most to 1 Hz, whereas those events that are observed at a low-latitude station may extent to several Hz. Simultaneous observations at several meridians extending over 100° show that the IPDP source region moves from east to west at a speed of 2-5° min^{-1}. There are necessarily no remarkable changes in frequency-time characteristics of IPDP pulsations. In the radial direction, IPDP wave frequency seems to be related to the He^{+} gyrofrequency in the equatorial plane. Observations are shown to be in general agreement with the evolution of the ion cyclotron instability in the plasma convection system of the magnetosphere. Several mechanisms seem to contribute simultaneously to the frequency shift of pulsations during IPDP events. (42 refs.)

110802 Longitudinal structure of substorm injections at synchronous orbit. R.L.Arnoldy, T.E.Moore (Space Sci. Center, Univ. of New Hampshire, Durham, NH, USA).
J. Geophys. Res. (USA), vol.88, no.A8, p.6213-20 (1 Aug. 1983).
From multiple-spacecraft measurements it is shown that the synchronous orbit manifestation of a substorm, i.e. plasma injection and magnetic field reconfiguration to dipolar, has an onset which expands both eastward and westward from a relatively narrow sector near midnight. For low-to-moderate geomagnetic activity the earliest onset sector at synchronous orbit is about 3 hours wide, skewed toward the evening side of midnight. Using a ground magnetometer network beneath the satellites, it is found that simultaneous westward motion of electrojet intensification is seen in the ground data over a larger longitudinal range than the magnetospheric signatures. This might be explained in terms of distortion of the nightside magnetic field at synchronous orbit. Plasma that has already been injected near midnight at synchronous altitude undergoes no further change as a result of the westward and eastward motion of the borders of the plasma. This suggests that the expansion does not represent new substorm activation. One can interpret these results in terms of an injection front wedge which makes hot plasma accessible to the inner magnetosphere and which spatially expands or propagates with time. (19 refs.)

110803 Particle and wave dynamics during plasma injections. H.C.Koons, J.F.Fennell (Space Sci. Lab., Aerospace Corp., Los Angeles, CA, USA).
J. Geophys. Res. (USA), vol.88, no.A8, p.6221-9 (1 Aug. 1983).
The SCATHA satellite measures particle and wave parameters as it moves outbound on the duskside from the plasmasphere into the plasma sheet. In many cases plasma waves are not observed in the quiescent plasma sheet prior to a plasma injection. The electron distribution function prior to entry into the plasma sheet is a nearly isotropic soft spectrum, $J(E) \sim 1/E$. Just inside the plasma sheet the spectrum begins to harden and becomes anisotropic, $J_{\perp} > J_{\parallel}$. As the satellite penetrates deeper into the plasma sheet, the spectrum further hardens, especially near $\alpha_0 \sim 90°$. At the injection the electron spectrum drastically hardens and often becomes peaked in the keV energy range. The pitch angle anisotropy is further enhanced in favor of $J_{\perp}$. The plasma wave emissions onset occurred as the time of the injection. Whistler mode waves are observed below the electron cyclotron frequency. Electrostatic waves are detected in bands between the electron cyclotron frequency harmonics. (20 refs.)

110804 An ISEE 3 high time resolution study of interplanetary parameter correlations with magnetospheric activity. D.N.Baker, R.D.Zwickl, S.J.Bame, E.W.Hones,Jr. (Los Alamos Nat. Lab., Los Alamos, NM, USA), B.T.Tsurutani, E.J.Smith, S.-I.Akasofu.
J. Geophys. Res. (USA), vol.88, no.A8, p.6230-42 (1 Aug. 1983).
From 1978 to 1982 the ISEE 3 spacecraft was in a 'halo' orbit around the Sun-Earth Lagrangian point L_1 approximately 240 R_E upstream of the Earth and was continuously in the upstream solar wind. In order to evaluate the efficacy of such a spacecraft as a real time interplanetary monitor to predict substorm activity and to measure solar wind energy input into the terrestrial magnetosphere, three periods in 1978 were selected in which to perform detailed correlation analyses between solar wind and interplanetary magnetic field (IMF) parameters and magnetospheric activity indices such as *AE* and *Dst*. High time resolution (1 min) averages of combined solar wind parameters and IMF parameters were used to perform linear cross-correlation analyses with the similarly averaged magnetospheric activity indices. A significant dependence of these results on levels of activity is found. (39 refs.)

110805 The season dependent distortions of the ring current. G.K.Mukherjee, R.Rajaram (Indian Inst. of Geomagnetism, Bombay, India).
J. Geomagn. & Geoelectr. (Japan), vol.34, no.11-12, p.619-32 (1982).
The seasonal variations of the plasma dynamics are investigated using the Mead-Fairfield model. It is shown that shifts in the mirror points and meridional drifts are introduced as a result of the season dependent tilt of the dipole axis with the Earth-Sun line. Other parameters like radial and azimuthal drifts and the bounce periods are free from seasonal variations. The maximum shift in the mirror points and latitudinal drifts are produced in particles bouncing close to the equator but the former peaks in the midnight meridian while the latter maximises (in magnitude) in the dawn and dusk sectors. A theoretical estimate is obtained for the seasonal geomagnetic variation associated with these distortions of the ring current. (16 refs.)

110806 A study of the mechanism of whistler-triggered VLF emissions. T.Yoshida, J.Ohtsu, M.Hayakawa (Res. Inst. of Atmospherics, Nagoya Univ., Aichi, Japan).
J. Geophys. (Germany), vol.53, no.1, p.59-67 (1983).
The conditions for triggering VLF emission by a natural whistler are studied, in terms of the length of interaction between whistler and electron determined by the unperturbed phase variation resulting from the spatial inhomogeneity and wave frequency variation. The computations are performed for a realistic magnetospheric model at $L=4.0$. It is found that the highest probability of VLF emission triggering occurs at an initial frequency slightly above 3 kHz in the whistler spectrum at a geomagnetic latitude $\sim -15°$ on the upstream side of the electron. (19 refs.)

110807 Resonance backscattering effect in the magnetospheric plasma. V.V.Krechetov, O.A.Mal'tseva, O.A.Molchanov (Inst. of Terrestrial Magnetism, Ionosphere, & Radio-wave Propagation, Acad. of Sci., Ukrainian SSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.10, p.786-90 (Oct. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.10, p.1103-8 (Oct. 1982). [received: Sept. 1983]
The effect of resonance backscattering of the signal (BSS) of a subauroral VLF transmitter ($L\approx4$) in the magnetosphere is analyzed. The experimental setup is described and the results obtained are presented. The main statistical relationships of BSS reception as a function of geomagnetic activity and local time are discussed. The BSS mechanism is discussed and ray trajectories, amplitude characteristics, BSS delays, and the zones of resonance absorption of the VLF signal are calculated. (15 refs.)

110808 Mechanism of nonlinear channelling of low-frequency waves. O.A.Molchanov, O.A.Mal'tseva, I.E.Sharko (Rostov-on-Don State Univ., Rostov-on-Don, USSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.10, p.790-4 (Oct. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.10, p.1109-14 (Oct. 1982). [received: Sept. 1983]
The possibility of nonlinear channelling of low-frequency waves in the Earth's magnetosphere in the process of merging with ion-cyclotron waves is considered. The characteristics of the merging process are determined and the channeling effect of the mechanism is demonstrated using the method of calculation of wave trajectories. (7 refs.)

110809 Near-equatorial magnetospheric particles from ~1 eV to ~1 MeV. D.T.Young (Los Alamos Nat. Lab., Los Alamos, NM, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.402-18 (March 1983).
Discusses near-equatorial populations of charged particles found within the Earth's magnetosphere. The review treats all aspects of near-equatorial particles. The structure of the report is based on a division of the near-equatorial particles into five populations: plasmasphere, suprathermal, plasma sheet, ring current, radiation belt. (271 refs.)

110810 Plasma boundaries and shocks. C.T.Russell (Inst. of Geophys. & Planetary Phys., Univ. of California, Los Angeles, CA, USA), E.W.Greenstadt.
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.449-62 (March 1983).
The authors discuss the bowshock, foreshock, interplanetary shocks, magnetosheath, magnetopause, boundary layer, plasma sheet, neutral sheet, polar cusp and plasma injection in magnetosphere. (273 refs.)

110811 Energy transfer in the quiet and disturbed magnetosphere. J.L.Burch (Dept. of Space Sci., Southwest Res. Inst., San Antonio, TX, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.463-73 (March 1983).
Progress on magnetospheric energy transfer reported during the 1979-82 quadrennium is reviewed. A discussion of the macroscopic control of magnetospheric phenomena by solar-wind dielectric and magnetic fields and kinetic pressure is followed by sections on energy transfer processes at the dayside magnetopause, in the magnetotail, near geosynchronous orbit, and at altitudes of $\approx1\ R_E$ above the auroral oval. Rapid progress in these areas has been stimulated primarily by ISEE and S3-3 observations and by the development of techniques for the large-scale computer simulation of plasma phenomena. (441 refs.)

110812 Modeling planetary magnetospheres. R.J.Walker (Inst. of Geophys. & Planetary Phys., Univ. of California, Los Angeles, CA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.495-507 (March 1983).
Advances in the development of models of the macroscopic properties of the magnetosphere are reviewed. The development of semiempirical models of the magnetospheric magnetic and electric fields is discussed. Models of magnetospheric storms and substorms in the inner magnetosphere and the magnetotail and reconnection are discussed. Global magnetohydrodynamic models of the interaction of the solar wind with the magnetosphere and five models of the magnetospheres of other planets are reported. (165 refs.)

94.40 COSMIC RAYS

110813 Approximation solutions of the equations of motion of a charged particle in the field of a magnetic dipole. P.E.Kustaanheimo, J.Tutein (Danmarks Ingeniorakad., Lyngby, Denmark).
Astron. Nachr. (Germany), vol.304, no.3, p.125-31 (1983).
Three first-order differential equations which determine the trajectory are deduced. An approximate integration by means of elementary functions yields a set of formulae that give a 'window' in the sky inside which the source of a high energy cosmic ray must lie. (5 refs.)

110814 Overview of cosmic ray studies and associated topics (1979-1982). M.A.Shea (Air Force Geophys. Lab., Hanscom AFB, Bedford, MA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.R119-83003 (March 1983).
Discusses solar cosmic ray emission and the Solar Maximum Mission. Interplanetary propagation characteristics are discussed together with the interactions with the Earth's magnetosphere. Galactic cosmic ray abundances and origins are discussed. Future developments are discussed. (no refs.)

94.40C Origin and propagation outside the solar system

110815 Implications of HEAO 3 data for the acceleration and propagation of galactic cosmic rays. J.F.Ormes, R.J.Protheroe (Lab. for High Energy Astrophys., NASA Goddard Space Flight Center, Greenbelt, MD, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.756-64 (15 Sept. 1983).
Reexamines the energy dependence of the mean escape length of cosmic rays from the Galaxy in the light of measurements of cosmic-ray abundances from the Danish-French experiment on *HEAO* 3. Comparing these data with results of propagation calculations, it is found that the energy dependence is steeper than previously thought. The authors discuss implications for the shape of the cosmic ray path length distribution at short path lengths and on the galactic wind model for the loss of cosmic rays from the Galaxy by convection. (70 refs.)

110816 Release of protons with energy $>10^{18}$eV from intergalactic magnetic field into interstellar magnetic field. A.K.Dasgupta (Federal Univ. of Technol., Bauchi, Nigeria).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.171-5 (July 1983).
Drift instabilities arising when accelerated protons are trapped in the intergalactic medium are examined. If α, the ratio of total (plasma+energetic particles) pressure and magnetic field pressure is larger than some value $\alpha\simeq0.1$ to 0.3, the magnetic trap is destroyed and protons are released into interstellar medium. If $\alpha<\alpha^*$, the trapped protons exhibit gradient instability due to magnetic drift resonance. This 'universal' instability results in rapid development of strong Alfven wave turbulence with small wavelengths transverse to the magnetic field. Particle diffusion due to the waves has a rather complicated character and appears to be weak as compared to quasilinear diffusion. (7 refs.)

110817 Boundary conditions for energetic particle transport at shocks. G.M.Webb (Max-Planck-Inst. fur Aeronomie, Katlenburg-Lindau, Germany).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.163-71 (Aug. 1983).
Boundary conditions on the particle number density and current for energetic charged particles at a plane shock are derived, both for cases of scatter free propagation and convective-diffusive transport. The analysis is carried out for oblique shocks for which there is a frame of reference in which the electric field $\mathbf{E}=0$ everywhere. The boundary conditions are initially obtained in the $\mathbf{E}=0$ frame. The appropriate boundary condition in the observer's frame can then be obtained by Lorentz transformation. (34 refs.)

110818 Cosmic rays from the galactic centre. M.Giler (Phys. Dept., Univ. of Lodz, Lodz, Poland).
J. Phys. G (GB), vol.9, no.9, p.1139-49 (Sept. 1983).
An old model for the origin of cosmic rays is reinvestigated. It is shown that under the assumption of repeated explosions in the galactic centre separated in time by 10^7 yr, the last one being 10^6 yr ago, a number of observed cosmic-ray properties can be reproduced. Acceptable fits appear for the form of the energy spectrum of protons from 1-10^8 GeV and the mean grammage. The long-term near-constancy of the intensity is understandable. However, the observed anisotropy and the grammage distribution can be accounted for only if the diffusion in the disc is much smaller than that in the halo. (23 refs.)

110819 Ultrahigh-energy cosmic rays. S.N.Vernov, G.B.Khristiansen (Sci. Res. Inst. of Nuclear Phys., Moscow Univ., Moscow, USSR).
Moscow Univ. Phys. Bull. (USA), vol.37, no.6, p.1-11 (1982). Translation of: *Vestn. Mosk. Univ. Ser. 3 (USSR)*, vol.37, no.6, p.3-11 (1982).
The authors present the results of a study of the primary very-high-energy cosmic radiation. They briefly explain the new methods which were realized. Particular attention is given to the results on the high energy spectrum of primary cosmic radiation in the interval of energies 10^{15}-10^{19} eV. The role of galactic cosmic rays of metagalactic origin is discussed, and also new mechanisms which ensure the acceleration of particles to energy of the order of more than 10^{19} eV. (31 refs.)

110820 The elemental and isotopic composition of galactic cosmic ray nuclei. R.A.Mewaldt (California Inst. of Technol., Pasadena, CA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.295-305 (March 1983).
Discusses progress in addressing the following question: In what ways is the composition of the matter that gets accelerated to be cosmic rays similar to, or different from, the composition of Solar System matter? The answers to this question are providing important new quantitative clues to the origin and evolution of this high-energy sample of matter from the Galaxy. The report is divided into three main sections, covering the composition of: 1) elements with nuclear charge $Z\leq28$; 2) ultraheavy ($Z\geq30$) nuclei; and 3) cosmic ray isotopes. (102 refs.)

94.40E Interplanetary propagation and effects

110821 Variations of cosmic-ray energy in interplanetary space. L.I.Dorman, M.E.Katz, Yu.I.Fedorov, B.A.Shakhov.
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.43-95 (July 1983).
A consistent theory of energy exchange between high-energy charged cosmic-ray particles and the random inhomogeneities of a magnetic field frozen in the moving solar wind plasma is developed. It is shown that the mode of

the particle energy variations at a given law of plasma velocity variation in space is determined by the specific form of the particle distribution function. The equation for the density of cosmic-ray energy is obtained. Consideration is given to the generation of a charged particle energy spectrum in the course of multiple scatterings by the random inhomogeneities of the magnetic field. (39 refs.)

94.40H Energetic solar particles and photons

110822 The association of energetic particles and shocks in the heliosphere. M.A.Lee (Space Sci. Res. Center, Univ. of New Hampshire, Durham, NH, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.324-8 (March 1983).
Reviews the theory of shock acceleration and extensions of that theory developed during the last four years and recent observations and applied theoretical work on energetic particle enhancements in association with each shock or class of shocks within the heliosphere. The Earth's bow shock and other planetary bow shocks are discussed. Corotating events and shocks produced by large solar flares which propagate through the Sun's corona and out through interplanetary space are considered. Shock-spike events, post-shock enhancements, and energetic storm particle events which have all been observed from 0.3 AU to 25 AU are discussed. The origin of solar cosmic rays is discussed. The author addresses the solar wind termination shock. (145 refs.)

94.40K Solar modulation and geophysical effects

110823 Interaction mean-free-path of cosmic-ray Fe in air. J.H.Crane, D.D.Guo, M.H.Israel, J.Klarmann (Dept. of Phys., Washington Univ., St. Louis, MO, USA).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.201-9 (July 1983).
The interaction mean-free-path of cosmic-ray iron in air is determined by observing the change in flux as a function of atmospheric depth. A large detector and a large variation in altitude during the balloon flight result in a high precision measurement. The result is in agreement, though slightly larger than the mean-free-path deduced from the measurements of interactions of iron on different targets at the Bevalac accelerator. (20 refs.)

110824 Abundance of cosmic-ray elements from sulfur to nickel as a function of atmospheric depth. J.H.Crane, M.H.Israel, J.Klarmann (Dept. of Phys., Washington Univ., St. Louis, MO, USA), J.F.Ormes, R.J.Protheroe.
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.211-22 (July 1983).
The measured elemental composition of cosmic rays with charge $16\leq Z\leq 28$ as a function of atmospheric depth is compared with a propagation calculation including energy loss. The resulting composition at the top of the atmosphere has better precision than previously possible on balloon borne experiments, and agrees well with the only satellite data available in this charge range. The extrapolation method also provides checks on assumed cross-sections for interactions of cosmic rays in air. (21 refs.)

110825 The composition, propagation and acceleration of energetic solar particles: a review of United States research 1979-1982. R.E.McGuire (NASA Goddard Space Flight Center, Greenbelt, MD, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.305-18 (March 1983).
Discusses major developments in American research related to solar energetic particles, both observational and theoretical, during the last four years (late 1978 to late 1982). The organization of the review is divided into three major sections, loosely defined on the basis of (1) time independent measurement (e.g. solar event-averaged elemental, isotopic and charge state composition, electron and ion spectra), (2) time dependent measurement (e.g. intensity and anisotropy versus time, at multiple energies and for multiple species) subdivided into the topics of interplanetary propagation and coronal transport/storage, and (3) the question of the injection and primary acceleration mechanisms. (197 refs.)

110826 Cosmic-ray modulation and the anomalous component. F.C.Jones (Lab. for High Energy Astrophys., NASA/Goddard Space Flight Center, Greenbelt, MD, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.318-24 (March 1983).
Discusses advances in cosmic-ray modulation observation and theory and in the study of the anomalous component of the cosmic radiation. It concentrates primarily on advances made in American research and reported in the open literature during the years 1979-82. (87 refs.)

110827 Pulsations of cosmic rays before solar proton bursts from ground-based observational data. S.A.Starodubtsev, A.T.Filippov, N.P.Chirkov (Inst. for Cosmosphys. Res. & Aeronomy, Acad. of Sci., USSR).
Sov. Astron. (USA), vol.26, no.6, p.736-7 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1229-30 (Nov.-Dec. 1982).
Fluctuations of the neutron component of cosmic rays during 11 solar flares in the period from 1967 to 1981 are investigated on the basis of five-minute data of ground stations. It is found that pulsations of cosmic rays with periods of 30-40, 60-90, and, rarely, 120-160 min are observed a day before the rise in the flux of relativistic particles from a solar flare. (3 refs.)

Photon and helium energy spectra above 1 TeV for primary cosmic rays .... See Entry 110828

94.40L Composition and energy spectra

110828 Photon and helium energy spectra above 1 TeV for primary cosmic rays. T.H.Burnett (Inst. for Cosmic Ray Res., Univ. of Tokyo, Tokyo, Japan), S.Dake, M.Fuki, J.C.Gregory, T.Hayashi, R.Holynski, R.W.Huggett, S.D.Hunter, J.Iwai, W.V.Jones, A.Jurak, J.J.Lord, O.Miyamura, H.Oda, T.Ogata, T.A.Parnell, T.Saito, T.Tabuki, Y.Takahashi, T.Tominaga, J.W.Watts, B.Wilczynska, R.J.Wilkes, W.Wolter, B.Wosiek.
Phys. Rev. Lett. (USA), vol.51, no.11, p.1010-13 (12 Sept. 1983).
Energy spectra of protons and helium nuclei in the primary cosmic rays were measured above 1 TeV in a series of balloon flights of emulsion chambers. Differential spectra may be represented by power laws of indices -2.81 ± 0.13 and -2.83 ± 0.20 for protons and He, respectively. No index charge was observed for either species over the energy ranges 5-500 TeV for protons and 2-50 TeV/nucleon for He. Intensities were consistent with extrapolations of previously published data below 1 TeV/nucleon. (18 refs.)

110829 An underground search for anomalous penetrating particles such as massive magnetic monopoles. T.Mashimo, S.Orito, K.Kawagoe, S.Nakamura, M.Nozaki (Dept. of Phys., Faculty of Sci., Univ. of Tokyo, Tokyo, Japan).
Phys. Lett. B (Netherlands), vol.128B, no.5, p.327-32 (1 Sept. 1983).
The authors have searched for anomalous cosmic-ray particles in a wide velocity range ($3\times10^{-4}<\beta<1$) by accurately measuring the time of flight and the dE/dx of downward and upward particles with six layers of scintillator hodoscopes placed 250 m underground. No anomalous candidate has been found other than the relativistic muons, setting an upper limit on the flux of 1.5×10^{-12} cm^{-2} s^{-1} sr^{-1} for magnetic monopoles in the velocity range $6\times10^{-4}<\beta<1$. Similar upper limits on the flux are obtained also for slow massive integrally- or fractionally-charged particles and also for relativistic fractionally-charged leptons. (22 refs.)

110830 Rigorous saddle-point method for cosmic-ray integral electron spectra. J.Sidhanta (Dept. of Phys., Charuchandra Coll., Calcutta, India), R.K.Roychoudhury, D.P.Bhattacharyya.
Phys. Rev. D (USA), vol.28, no.5, p.1113-16 (1 Sept. 1983).
It is established here that the saddle-point method of contour integration, when applied with more than customary rigor, gives a new general formula for integral electrons spectra for electron-initiated showers. The lowest-order approximation to this general formula, though much simpler than those widely used, exactly reproduces the curves represented by the latter. (2 refs.)

94.40N Extensive air showers

110831 Derivation of gamma ray spectrum at high altitude from the recent primary cosmic ray spectrum using gamma ray bundle extensive air shower results and electromagnetic cascade theory. D.P.Bhattacharyya, A.Mukhopadhyay, P.Pal (Dept. of Theoretical Phys., Indian Association for the Cultivation of Sci., Calcutta, India), R.K.R.Choudhury.
Indian J. Phys. Part B, vol.57B, no.2, p.166-76 (April 1983). [received: Sept. 1983]
The flux and energy spectrum of electromagnetic component like gamma rays in the energy region 0.5-10 TeV has been calculated from the authors' primary cosmic ray spectrum. This is based on the chemical composition data of Japanese American Cooperative Emulsion Experiments and Goddard Space Flight Centre results viz. the total primary nucleon spectrum follows the form. (17 refs.)

110832 High-energy hadrons in extensive air showers. B.V.Sreekantan, S.C.Tonwar, P.R.Viswanath (Tata Inst. of Fundamental Res., Colaba, Bombay, India).
Phys. Rev. D (USA), vol.28, no.5, p.1050-66 (1 Sept. 1983).
Various attempts to interpret the experimental results on high-energy hadrons in extensive air showers of size $\sim10^5$-10^6 at mountain altitudes in terms of the characteristics of high-energy particle interactions have yielded ambiguous results due to apparently large differences between results from different experiments using different types of hadron detectors. In an attempt to understand these differences the authors have studied the response of different types of detectors to showers with multiple hadrons incident over the detector area. The simulations suggest that large-area nonvisual detectors overestimate the energies of high-energy hadrons. The energy overestimation depends on the type and the size of the detector, the energy of the high-energy hadron, the shower size, and the observational altitude. They discuss the results from the experiment at mountain altitude laboratory at Ooty where they have studied this problem by comparing the response of a burst detector placed inside a multiplate cloud chamber with the visual information from the chamber. The observations show that large discrepancies between the results from different experiments are mostly due to the differences between the response functions of the detectors and that measurements with visual detectors give the most reliable data on the number of high-energy hadrons in air showers. They also show that three experiments which have used burst detectors agree well with each other and with the cloud-chamber experiment if appropriate corrections are applied. They have compared these measurements with the expectations from Monte Carlo simulations of air showers using scaling models for high-energy particle interactions and find that the observed number of hadrons in a shower are too few compared to the expected number. They show that changes in the interaction model which affect only particles in the central region do not have any significant effect on the expected number of high-energy hadrons in a shower. These results imply that either hadron-air-nucleus collisions are very different at high energies $\sim10^6$ GeV in the fragmentation region compared to hadron-hadron collisions or there is substantial violation of scaling in the fragmentation region in hadron-hadron interactions at air-shower energies. (46 refs.)

94.40R High-energy interactions

110833 Interaction with a large multiplicity registered in photoemulsion. V.A.Sobinyakov, Ch.A.Tret'yakova, V.Ya.Shestoperov (Sci. Res. Inst. of Nuclear Phys., Moscow Univ., Moscow, USSR).
Moscow Univ. Phys. Bull. (USA), vol.37, no.6, p.89-90 (1982). Translation of: *Vestn. Mosk. Univ. Ser. 3 (USSR)*, vol.37, no.6, p.77-8 (1982).
The authors present the results of measurements of angles of 527 relativistic particles which are created in the interaction of an aluminum nucleus with the nucleus of the photoemulsion. (5 refs.)

110834 Inelasticity of nucleus-nucleus collisions and composition of high-energy cosmic rays. T.K.Gaisser, T.Stanev (Bartol Res. Found., Franklin Inst., Univ. of Delaware, Newark, DE, USA).
Phys. Rev. D (USA), vol.28, no.3, p.464-7 (1 Aug. 1983).
Current experiments to determine the chemical composition and energy spectra of primary-cosmic-ray nuclei around 10^{14} eV maximize collecting power by using thin calorimeters of large area that measure primarily the electromagnetic fraction of the energy released when the nucleus interacts. Estimates of this fraction are model-dependent and differ by nearly a factor of 2 for a range of reasonable models. The authors discuss the consequences of this for composition studies using emulsion chambers. (16 refs.)

94.40T Muons and neutrinos

110835 Neutrino energy production spectra in a relativistic plasma. F.Giovannelli (Inst. of Space Astrophys., CNR, Frascati, Italy), S.Karakula, W.Tkaczyk.
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.121-5 (Aug. 1983).
Determines the neutrino and antineutrino energy production spectra in a relativistic plasma. The considered plasma temperature range is 10^{11}-10^{13}K. The maximum of the neutrino energy production spectrum is at the energy $E_{\nu}=31$ MeV. The antineutrino and electron-neutrino production spectra from μ^{+} decay have maxima at 40 MeV. The cooling rate coefficient for a relativistic plasma emitting neutrinos is considered for various mean kinetic energies of the protons. The energy attenuation time for a relativistic plasma is estimated and briefly discussed. (18 refs.)

110836 Momentum flux invariance in the solar wind. D.J.Mullan (Bartol Res. Found., Franklin Inst., Univ. of Delaware, Newark, DE, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.325-8 (1 Sept. 1983).
Uses *ISEE C* data to confirm the result of Steinitz and Eyni (1980) that the momentum flux in the solar wind is invariant relative to velocity structures. (3 refs.)

110837 Corotating pressure waves without fast streams in the solar wind. L.F.Burlaga (Lab. for Extraterrestrial Phys., NASA Goddard Space Flight Center, Greenbelt, MD, USA).
J. Geophys. Res. (USA), vol.88, no.A8, p.6085-94 (1 Aug. 1983).
Voyager 1 and 2 magnetic field and plasma data are presented which demonstrate the existence of large scale, corotating, nonlinear pressure waves between 2 AU and 4 AU that are not accompanied by fast streams. The pressure waves are presumed to be generated by the interaction between fast corotating streams and slower flows near the Sun. For two of the three pressure waves that are discussed, the absence of a relatively fast stream is probably a real, physical effect, viz. a consequence of deceleration of the stream and acceleration of the ambient flow by the associated compression wave. For the third pressure wave, the apparent absence of a stream may be a geometrical effect. It is suggested that the development of large-scale, nonlinear pressure waves at the expense of part of the kinetic energy of streams produces a qualitative change in the solar wind in the outer heliosphere. (39 refs.)

110838 Alfven solitons in the solar wind. C.R.Ovenden, H.A.Shah, S.J.Schwartz (Dept. of Appl. Math., Queen Mary Coll., London, England).
J. Geophys. Res. (USA), vol.88, no.A8, p.6095-101 (1 Aug. 1983).
The interaction of circularly polarized Alfven waves in the surrounding plasma in high speed solar wind streams is investigated. Alfven wave modulation instability is discussed and nonlinear envelope soliton solutions of the magnetohydrodynamic equations are introduced. The characteristics of these Alfven solitons are compared with observational results obtained from helios I and II. A model of the expected turbulent spectrum due to a collection of such solitons is constructed and its radial dependence is investigated, again along with comparison to Helios data. (28 refs.)

110839 Coupled hydromagnetic wave excitation and ion acceleration at interplanetary traveling shocks. M.A.Lee (Space Sci. Center, Univ. of New Hampshire, Durham, NH, USA).
J. Geophys. Res. (USA), vol.88, no.A8, p.6109-19 (1 Aug. 1983).
A self-consistent theory is presented for the excitation of hydromagnetic waves and the acceleration of ions upstream of interplanetary traveling shocks. The waves are excited by the ions by virtue of ion streaming relative to the solar wind; the ions are accelerated by being coupled to the compression of the shock via pitch angle scattering on the upstream waves and the downstream turbulence. Diffusion equations describing the ion transport and wave kinetic equations describing the hydromagnetic wave transport are solved self-consistently to yield analytical expressions for the differential wave intensity spectrum as a function of wave number k and distance z upstream of the shock and for the ion omnidirectional distribution functions and anisotropies as functions of energy E and z. This theory is in quantitative agreement with observations. (59 refs.)

110840 Solar cycle and long term changes in the solar wind. J.Feynman (Dept. of Phys., Boston Coll., Chestnut Hill, MA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.338-48 (March 1983).
During the last four years substantial progress has been made in the study of variations of the solar wind on time scales of decades to hundreds of years. Solar cycle changes in 3 dimensions have been described and the cyclic evolution of solar sources studied. Work on longer term changes has made a good start. Data sets and methods of scientific analysis are being developed. Estimates have been made of pre-space-age solar wind properties. The existence of the solar wind properties. The existence of the eleven year cycle for the last 1500 years was studied. The non-random nature of variations over many solar cycles was confirmed but there is still controversy concerning the periodic nature of the 80-100 year variation. There is evidence that variations of the Maunder and Sporer types may be periodic. (83 refs.)

110841 Heliospheric magnetic fields and plasmas. L.F.Burlaga (Lab. for Extraterrestrial Phys., NASA/Goddard Space Flight Center, Greenbelt, MD, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.363-75 (March 1983).
Surveys the literature on the subject of heliospheric physics for the period 1979-82. It consists of two distinct parts: a comprehensive bibliography of US efforts in heliospheric physics and a narrative description of the principal results. The bibliography includes relevant papers in English by European and Japanese scientists, but does not cover all the work in this field. The author focuses on observations and theories related to the study of the heliosphere as a large-scale astrophysical system which forms part of the Earth's environment. (242 refs.)

(see also 87.65 Aerospace biophysics and medical physics)

110842 4 probes to Comet Halley. J.Eichenlaub.
Astronomy (USA), vol.11, no.9, p.16-22 (Sept. 1983).
Discusses the nature of Comet Halley (1982i) in relation to the four proposed spacecraft missions Giotto, Planet A, (Vega 1 and Vega 2) and ISEE-3. Each mission is briefly described. (no refs.)

110843 Polar orbiting satellites. II. T.Weatherley.
Radio & Electron. World (GB), p.40-1 (Aug. 1983).
For pt.I see ibid., vol.2, no.6, p.17 (1983). To predict when a satellite can be heard from a given location, it is necessary to have certain reference parameters. The minimum requirements are the orbital period, and the time and point at which the satellite crosses the equator. Using data for the NOAA7 a worked example is included, and a utility program for the BBC micro is given. (no refs.)

110844 Weather satellite reception. II. W.Poel.
Radio & Electron. World (GB), p.52-7 (Aug. 1983).
For pt.I see ibid., vol.2, no.9, p.57 (1983). Examines the baseband requirements for Meteosat reception. There are two readily available converters for 1.8 GHz, one from Microwave Modules and the other from VHF Communications. The latter is described. The APT/WEFAX signal is firstly filtered in a bandpass filter and demodulated. The analogue video signal is sampled and converted in an 8-bit ADC. Only 6 bits are required for the grey levels, which are then converted into a serial format. Synchronization is obtained from the 2.4 kHz sub-carrier and all signals are obtained from a PLL. This is followed by a chain of dividers. (no refs.)

110845 The critical inclination problem with small eccentricity. II. Application to Earth satellites. A.H.Jupp (Dept. of Appl. Math. & Theoretical Phys., Univ. of Liverpool, Liverpool, England), A.Y.Abdulla.
Celestial Mech. (Netherlands), vol.30, no.3, p.297-308 (July 1983).
For pt.I see ibid., vol.21, no.4, p.361-93 (1980). The general theory described in an earlier paper is used to investigate the long-term behaviour of the eccentricity and argument of the perigee for Earth satellites which have nearly circular orbits and orbital inclinations in the neighbourhood of the critical value 63.4°. Taking into account the effect of all the zonal harmonics, it is shown that there are just two types of behaviour possible, compared with the six described in the earlier general theory and the four found by Aoki (1963). (5 refs.)

110846 A linear solution of the equations of motion of an Earth-orbiting satellite based on a Lie-series. D.J.Lelgemann (Inst. fur Angewandte Geodasie, Frankfurt, Germany).
Celestial Mech. (Netherlands), vol.30, no.3, p.309-21 (July 1983).
Using Hill's variables, an analytical solution of a canonical system of six differential equations describing the motion of a satellite in the gravitational field of the Earth is derived. The gravity field expanded into spherical harmonics, has to be expressed as a function of the Hill variables. The intermediary is chosen to include the main secular terms. The first order solution retains the highly practical formal structure of Kaula's (1966) linear solution, but is valid for circular orbits and provides a spectral decomposition of radius vector and radial velocity. The resulting eccentricity functions are much simpler than the Hansen functions, since a series evaluation of the Kepler equations is avoided. The solution obtained may be extended to higher order solutions by Hori's perturbation method. (8 refs.)

110847 Advanced low altitude infrared Earth sensors. T.K.Alex, Y.K.Jain, K.Kanakaraju, J.A.Kamalakar (ISRO Satellite Centre, Dept. of Space, Government of India, Bangalore, India).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.366, p.140-7 (1983). (Modern Utilization of Infrared Technology VIII, San Diego, CA, USA, 26-27 Aug. 1982).
Novel low altitude infrared Earth sensors are described. A static horizon sensor utilises the state of art technology in electronics to minimise the effect of radiance gradient by taking the ratio of the radiometric signals by a hard wired or microprocessor based system. A scanning sensor is also being developed which scans radially at four edges and which using a single scan assembly thus reducing errors caused by conventional techniques. (no refs.)

110848 The ISPM mission: science objectives and mission overview. K.-P.Wenzel, R.G.Marsden (Space Sci. Dept., ESA, ESTEC, Noordwijk, Netherlands), E.J.Smith.
ESA J. (Netherlands), vol.7, no.2, p.123-34 (1983).
The International Solar Polar Mission (ISPM) will, for the first time, allow exploration of the heliosphere within a few astronomical units of the Sun over the full range of heliographic latitudes. The prime mission objective is to study, as a function of solar latitude, the properties of the interplanetary medium and solar corona. The scientific instrumentation is designed to explore, in the third heliospheric dimension, the properties of the solar wind, the Sun/wind interface, the heliospheric magnetic field, solar radio bursts and plasma waves, solar X-rays, solar and galactic cosmic rays, and interplanetary/interstellar neutral gas and dust. ISPM will also detect cosmic gamma-ray bursts and search for gravitational waves. ISPM is a cooperative mission carried out jointly by ESA and NASA, to be launched in May 1986 and utilising a Jupiter gravity-assist to achieve a high-solar latitude trajectory. (7 refs.)

110849 Nodal period of a satellite perturbed by the Earth's oblateness. E.A.Roth (Mission Analysis Office, European Space Operations Centre, Darmstadt, Germany).
ESA J. (Netherlands), vol.7, no.2, p.189-93 (1983).
The first-order formula for the nodal period of a satellite orbit perturbed by the oblateness (J_2) of the central body is derived. The result is valid for all eccentricities $0 \leq e < 1$ and all inclinations $0 \leq i \leq \pi$, with an error of the order of $0(J_2^2)$. (5 refs.)

110850 Infrared astronomy: spy in space. R.A.J.Arthur.
Funkschau (Germany), no.14, p.52 (8 July 1983). In German.
Gives a brief report on the joint European IRAS satellite, equipped with a helium-cooled infrared telescope for operations in the 8 to 120 μm range from an orbiting height of 900 km. The terrestrial control station is at Chilton, South England. The 12 m parabolic antenna at Chilton is shown. (no refs.) *A.L.*

110851 Dynamics of momentum biased spacecraft in a near-polar orbit. R.G.Sellappan (Spacecraft Engng. Dept., RCA American Communications Inc., Princeton, NJ, USA).
IEEE Trans. Aerosp. & Electron. Syst. (USA), vol.19, no.3, p.360-8 (May 1983).
The equations of motion of a momentum biased spacecraft are derived in a general form. The spacecraft is assumed to be orbiting in a near-elliptical orbit. An aerodynamic torque model which accounts for the atmospheric superrotation is assumed. The equilibrium attitude angles are obtained in terms of modified Bessel functions. Analytic expressions for the long-term motion of the momentum biased axis are derived for special case. The analysis is applicable to the Magsat mission. (7 refs.)

110852 Meteorological satellite and its image processing techniques. M.Narui (Meteorological Satellite Centre, Tokyo, Japan).
J. Inst. Telev. Eng. Jpn. (Japan), vol.37, no.3, p.186-94 (March 1983). In Japanese.
This paper briefly describes the construction of the visual infrared spin scan radiometer (VISSR) on the HIMAWARI geostationary geological satellite (GMS) and outlines the image processing method of data sets issued from the VISSR. The VISSR is provided with the Ritchey-Chretien optical system and the scanning mirror servocontrolled by means of a torque motor and optical encoder. The data sampling rate is 437.5K samples per second for visual observation and 109.4K samples per second for infrared. The VISSR signals from the GMS are received and demodulated by a command and data acquisition system (CDAS) on ground. The stretched VISSR signals transmitted from the CDAS through a microwave line are fed to a computer system to provide images for transmission to news organisations. (no refs.) *K.B.*

110853 The Voyager mission to Uranus and beyond. S.J.Kerridge (Jet Propulsion Lab., Pasadena, CA, USA).
J. Br. Interplanet. Soc. (GB), vol.36, no.8, p.339-45 (Aug. 1983).
On 24 January 1986 the Voyager 2 probe will approach within 82000 km of the cloud tops of the planet Uranus, obtaining our first closeup pictures of this giant outer planet as well as amassing large quantities of data from the ten other onboard experiments. Closeups of the five presently known Uranian satellites will be transmitted back over a distance of 20 AU with a one-way light-time of two and three-quarter hours. The narrow, elliptical, inclined rings of Uranus will be probed both by the imaging subsystem and by the photopolarimeter detecting the light of stars shining through this diffuse necklace. (no refs.)

110854 Exosat—the new extrasolar X-ray observatory. H.A.Hoff.
J. Br. Interplanet. Soc. (GB), vol.36, no.8, p.363-7 (Aug. 1983).
A history of the Exosat mission is discussed. The equipment on board is described and the satellite's operation is considered. (2 refs.)

110855 Geosynchronous satellite list: 1983. W.L.Morgan (Communications Centre of Clarksburg, Clarksburg, MD, USA).
J. Br. Interplanet. Soc. (GB), vol.36, no.8, p.377-82 (Aug. 1983).
Presents an update to the list of Morgan (1979). The table lists satellites by their orbital location. For a given position, the satellites appear on an ascending frequency basis. Only those satellites in use or planned for in the near future are listed. The list does not include inactive or non-communicating pieces of debris. (2 refs.)

110856 ERS-1: an ice and ocean monitoring mission. P.R.C.Gillett (Dornier System GmbH, Friedrichshafen, Germany).
J. Br. Interplanet. Soc. (GB), vol.36, no.9, p.387-93 (Sept. 1983).
The detailed definition phase for the European Space Agency's Remote-Sensing Satellite System, ERS-1, has been carried out by an industrial consortium of European and Canadian companies led by Dornier System of Germany. The author presents a summary of the mission and the system that has evolved, highlighting the characteristics of the main elements. (3 refs.)

110857 A proposal to use an upper atmosphere satellite tethered to the Space Shuttle for the collection of micro-meteoric material. G.J.Corso (Dept. of Phys. & Astron., Indiana Univ. Northwest, Gary, IN, USA).
J. Br. Interplanet. Soc. (GB), vol.36, no.9, p.403-8 (Sept. 1983).
The use of a satellite tethered to the Space Shuttle by a long cable is proposed for the collection of intact cosmic dust particles smaller than 2 microns impacting the collector surfaces at a velocity less than about 3 km/sec; and the study of impact craters and impact debris resulting from impacts of all sized particles at velocities in excess of 3 km/sec. The tether facility, now being developed by the Marshall Space Flight Center for use on the Shuttle around 1987, is capable of deploying satellites at the end of a cable approximately 100 km long. Several advantages of this new approach for the collection of intact particles smaller than 2 microns over both stratospheric and on-board Shuttle mounted or Long Duration Exposure Facility type collectors are discussed. (35 refs.)

110858 Advances in orbit theory for an artificial satellite with drag. J.J.F.Liu (SPACECOM, Peterson AFB, Colorado Springs, CO, USA).
J. Astronaut. Sci. (USA), vol.31, no.2, p.165-88 (April-June 1983).
The general problem of the motion of an artificial satellite with atmospheric drag and the mathematical formulation of the variational equations for this problem are revisited. Relevant advances for the analytic and semianalytic solutions of the coupled problem with drag are outlined. The author discusses the complex nature of the dynamical system and presents some of the existing solutions and their numerical results when available. (101 refs.)

110859 Linear wide angle Sun sensor for spinning satellites. M.P.Philip, B.Kalakrishnan, Y.K.Jain (ISRO Satellite Centre, Bangalore, India).
Opt. Eng. (USA), vol.22, no.4, p.491-6 (July-Aug. 1983).
The V-slit, N-slit, and crossed slit Sun sensors that are normally used for Sun elevation angle measurement on spinning spacecraft suffer from two defects, namely, nonlinearity of response and limitation in range. The authors describe a concept which overcomes both of these defects. Two versions of sensors based on this concept which give a linear output and have a range of nearly ±90° of elevation angle are described. The first version has already been flown on three Indian spacecraft, and a flight model of the second improved version is under testing for another satellite to be flown shortly. (no refs.)

110860 Near-circular satellite orbits in an oblate, diurnally varying atmosphere. G.G.Swinerd, W.J.Boulton (Dept. of Math., Univ. of Aston, Birmingham, England).
Proc. R. Soc. London Ser. A (GB), vol.389, no.1796, p.153-70 (8 Sept. 1983).
The influence of air drag and the geopotential on near-circular satellite orbits, eccentricity $e < 0.01$, is considered. A model of the atmosphere is adopted that allows for oblateness, and in which the density behaviour approximates to the observed diurnal variation. Differential equations governing the variation in e and the argument of perigee ω are derived by combining the effects of air drag with those of the Earth's gravitational field. These are solved numerically using initial conditions obtained from a series of computed orbits of the satellite 1963-27 A. The behaviour of the orbital elements predicted by the numerical solution is compared with the observed elements to test the developed theory, and to obtain values of atmospheric parameters at heights near 400 km. (23 refs.)

110861 A BASIC program for calculating satellite orbits. C.A.Huertas.
Rev. Telegr. Electron. (Argentina), vol.71, no.839, p.293-5 (April 1983). In Spanish.
Presents a BASIC program for the calculation of times of passage over Buenos Aires of the following twelve satellites: OSCAR 7, 8 and 9, RS 1, 2, 3, 4, 5, 6, 7, and 8, and NOAA-7. It requires a 3K memory (1.7K if the REM is suppressed and only a single satellite at a time is dealt with). It is very rapid in operation; starting with the specification of the satellite in question and the date, it gives in a few minutes the time and direction of appearance over the horizon, the direction of closest approach, the direction of disappearance, the maximum elevation, the time of passage and the crossing with Equator. (no refs.) *C.J.O.G.*

110862 Return to Jupiter: project Galileo. T.V.Johnson, C.M.Yeates (Jet Propulsion Lab., Pasadena, CA, USA).
Sky & Telesc. (USA), vol.66, no.2, p.99-106 (Aug. 1983).
Discusses the Galileo mission planned for launch in 1986. A description is given of the instrumentation on the probe and the chronological sequence at Jupiter encounter. The objectives of the mission are summarised. (no refs.)

95.00 FUNDAMENTAL ASTRONOMY AND ASTROPHYSICS, INSTRUMENTATION AND TECHNIQUES AND ASTRONOMICAL OBSERVATIONS

95.10 FUNDAMENTAL ASTRONOMY

110863 DE 102: a numerically integrated ephemeris of the Moon and planets spanning forty-four centuries. X.X.Newhall, E.M.Standish,Jr., J.G.Williams (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.150-67 (Aug. 1983).
An ephemeris of the Moon and nine planets is numerically integrated from 1411 BC to 3002 AD. The initial conditions for the simultaneous integration are based on fits to modern position measurements of the eight major planets and the Moon. The data include optical meridian transits, radar ranges, planetary spacecraft positions, and lunar laser ranges. The acceleration model for the integration is described and it is shown that the stability of the lunar integration depends upon simultaneously integrating the physical librations. A long ephemeris has utility for comparison with both historical observations and analytical theories. Comparison with numerical representations permits the equinox and obliquity of the ephemeris to be recovered. (74 refs.)

110864 On the determination of absolute right ascensions and declinations of groups of stars using minor planets. W.Landgraf.
Astron. Nachr. (Germany), vol.304, no.3, p.137-8 (1983). In German.
Presents a method to obtain the absolute positions of stars from observations of a minor planet with small eccentricity distributed over a short time and possibly over a geocentric loop in the field traversed by the minor planet. (no refs.)

110865 Positions of stars in regions of 14 southern galactic clusters. T.B.Andersen, A.Reiz (Copenhagen Univ. Obs., Copenhagen, Denmark).
Astron. & Astrophys. Suppl. Ser. (France), vol.53, no.2, p.181-214 (Aug. 1983).
Positions for a total of 3487 stars, scattered over 14 regions, are determined using the Danish 1.5-m telescope at La Silla. The 14 regions are centred on the southern galactic clusters NGC 1981, 2287, 2437, 2451, 2516, 2546, 2547, 2548, 3114, 3532, IC 2391, 2395, 2602, and Trumpler 10. Combining the Ritchley-Chretien reflector optics with a single element Schmidt-type corrector, gives a considerably enlarged flat field (radius about 25 minutes of arc, or 95 mm) with stellar images of excellent definition. A frame of reference is established for each region using ESO Schmidt plates centred on the clusters, each plate containing from 20 to 35 measurable Perth 70 stars. These objects serve for determining positions of some 200 to 400 fainter stars within a central field of 25 minutes of arc radius, covering the corresponding 1.5-m plates. The fainter stars serve as a secondary standard. An internal mean error in one plate position in the range 0.030 to 0.048 seconds of arc is derived. (20 refs.)

110866 The solar eclipse of 26 Febrary 1979: introductory comments. W.W.Berning (Phys. Sci. Lab., New Mexico State Univ., Las Cruces, NM, USA).
J. Atmos. & Terr. Phys. (GB), vol.45, no.7, p.423-5 (July 1983). (Meeting of the American Geophysical Union on the Total Solar Eclipse of 26 February 1979, Toronto, Ont., Canada, May 1980).
On 26 February 1979 a total solar eclipse occurred over North America, the last to occur this century over this continent. The eclipse began at dawn, west of Puget Sound, and terminated at sunset over northern Greenland. The path of totality crossed the northwestern tier of the United States, the Canadian provinces of Saskatchewan, Manitoba, Ontario and northern Quebec, Baffin Island and Greenland. Most observations were made from Red Lake, Canada. (8 refs.)

95.10C Celestial mechanics

(for dynamics and kinematics of stellar systems, see 98.10)

110867 Discrete mechanics: some remarks. E.Perozzi (Istituto di Astrofisica Spaziale, Rome, Italy).
Celestial Mech. (Netherlands), vol.30, no.3, p.249-61 (July 1983).
A detailed investigation of discrete mechanics (a numerical method developed by Greenspan and La Budde, 1973, 1974) in celestial mechanics applications is carried out. The method shows a remarkable precession of the argument of pericentre, whose value depends mainly on the time step scaling used and on the length of the integration step. It is found that this behaviour is due to the structure of discrete mechanics and that the precession, taken as a function of the length of the integration step, follows with good agreement an inverse square law. The existence of this relationship allows the development of a modified version of the method: its consistence with respect to the original one is discussed both from an analytical and a computational point of view. Furthermore the modified discrete mechanics allows the extension of the method to the case of the potential due to an oblate spheroid. (17 refs.)

110868 Special cases in the problem of two rigid bodies. G.N.Doubochine (Inst. Astronomique d'Etat, Moscow, USSR).
Celestial Mech. (Netherlands), vol.30, no.3, p.263-73 (July 1983). In French.
Two special cases in the problem of two rigid bodies are examined. In the first case two arbitrary bodies interact with a force, proportional to first degree of distance. In the second case, two spheres interact with a force proportional to some degree of distance. (1 ref.)

110869 Generalized f and g series and convergence of the power series solution of the n-body problem. D.N.Papadakos (Univ. Obs., St. Andrews, Scotland).
Celestial Mech. (Netherlands), vol.30, no.3, p.275-82 (July 1983).
The existence of power series, analogous to the familiar f and g-series of the two-body problem, is demonstrated in the case of the n-body problem, and recursive formulae are deduced for the derivation of the coefficients of these series. In addition a proof of the convergence of the power series solution of the n-body problem is given, based on the developed series. (16 refs.)

110870 A unified treatment of some expansion procedures in perturbation theory: Lie series, Faa di Bruno operators, and Arbogast's Rule. J.Murdock (Dept. of Math., Iowa State Univ., Ames, IA, USA).
Celestial Mech. (Netherlands), vol.30, no.3, p.283-95 (July 1983).
The problem of expanding the transform of a function under a near-identity change of coordinates is reviewed. A common derivation is given for Musen's (1965) Faa di Bruno operators and Kamel's (1970) Lie series, and both are related to Arbogast's Rule for composing power series. (6 refs.)

110871 Equations of motion of the restricted problem of three bodies with variable mass. A.K.Shrivastava, B.Ishwar (Dept. of Math., Indian Coll. of Engng., Motihari, Bihar, India).
Celestial Mech. (Netherlands), vol.30, no.3, p.323-8 (July 1983).
Deduces the differential equations of motion of the restricted problem of three bodies with decreasing mass, under the assumption of the mass of the satellite varies with respect to time. The authors apply Jeans law and the space time transformation contrast to the transformation of Meshcherskii. The space time transformation is applicable only in the special case $n=1$, $k=0$, $q={}^1/_2$. The equations of motion of the problem differ from the equations of motion of the restricted three body problem with constant mass only by small perturbing forces. (7 refs.)

110872 Necessary conditions for the existence of plane motions in the problem of translatory-rotary motion of two rigid bodies. II. V.V.Vidyakin.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.381-4 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Conditions are found in which the centres of mass of absolute rigid bodies possessing arbitrary internal structure and external form can have motion in an invariable plane. Necessary and sufficient conditions have been found for plane motions in the problem under study. (3 refs.)

110873 On the collinear libration points of the photogravitational three-body problem. A.L.Kunitsyn, A.T.Tureshbaev.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.432-5 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
The existence of a three-parameter family of the collinear-libration points in photogravitational three-body problem is shown. It is shown that contrary to the classical problem, the region of stability of the equilibrium positions in parametric space exists. (9 refs.)

110874 On the motion of gravitating bodies with the radiation reaction force taken into account. L.P.Grishchuk, S.M.Kopeikin.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.436-40 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Equations of motion for two spherically-symmetric nonrotating bodies are derived and solved in the $(v/c)^5$ approximation, where the radiation force first appears. An explicit expression for the force is given. The periodic and secular corrections to the Keplerian motion are found. It is shown that the invariant distance between the bodies diminishes secularly. (17 refs.)

110875 The averaged, hyperbolic, restricted three-body problem. A.B.Sorokovich (S. Lazo Polytech. Inst., Kishinev, USSR).
Sov. Astron. (USA), vol.26, no.6, p.721-6 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1200-11 (Nov.-Dec. 1982).
The plane, singly averaged, hyperbolic, restricted three-body problem in the case of small eccentricities of the perturbing body is analyzed in the article. The general solution of the linearized system of differential equations in the form of series in powers of the small parameter is found in the case when the first term is taken in the perturbation function. It is shown that stability of the unperturbed motion is retained when the orbital eccentricity of the perturbing body is relatively small and the perturbed body is sufficiently close to the central body. The exact and singly averaged problems are integrated numerically, and the linearized system is calculated on a computer from the equations of the general solution. The analytical and qualitative conclusions are confirmed by comparing the results obtained. (4 refs.)

110876 A nontraditional means of determining the orbital elements of unknown cosmic objects from the data of computer processing of survey photographs. V.IO.Kuryshev, N.I.Perov (State Pedagogical Inst., Ryazan, USSR).
Sov. Astron. (USA), vol.26, no.6, p.727-9 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1212-17 (Nov.-Dec. 1982).
A method of calculating the Keplerian elements of the orbits of artificial Earth satellites from five positions (α_k, δ_k, s_k, $k=0, 1, \ldots, 4$) is discussed. A distinctive feature of the proposed method is the absence from the working equations of series expanded in powers of time. (2 refs.)

110877 Some particular solutions of the restricted problem of three rigid bodies. E.N.Eremenko (M.V. Lomonosov State Univ., Moscow, USSR).
Sov. Astron. (USA), vol.26, no.6, p.730-3 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1218-24 (Nov.-Dec. 1982).
The problem of the translational-rotational motion of a triaxial rigid body is formulated in the restricted problem of three rigid bodies. The motion of the body is described by canonical osculating elements. The existence of particular regular solutions for the rigid body in a first approximation is established on the basis of the Gaussian averaging scheme. The question of the stability of these motions in the Lyapunov sense is investigated in a first approximation. (7 refs.)

95.30 FUNDAMENTAL ASPECTS OF ASTROPHYSICS

110878 Focusing of high-Mach number jets by an ambient medium. D.Eichler (Inst. for Theoretical Phys., Univ. of California, Santa Barbara, CA, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.48-53 (1 Sept. 1983).
It is argued that a precessing jet will, at some sufficiently large scale, be focused by an ambient plasma of finite pressure such that its angular spread on larger scales is much smaller than that of the precession cone at small scales. More generally, the collimation of a moderately wide jet can be sharpened by the ambient medium, and a smeared-out beam can be recollimated. Shapes of channels formed by such recollimated beams are calculated. The focal length along the precession axis is found to be nearly independent of the original opening angle if the other jet parameters are fixed. The results are compared with real sources where there is some observational evidence for jet focusing, such as SS 433. (20 refs.)

110879 Alfven wave collapse and the stability of a relativistic electron beam in a magnetized astrophysical plasma. S.R.Spangler, J.P.Sheerin (Dept. of Phys. & Astron., Univ. of Iowa, Iowa City, IA, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.273-8 (1 Sept. 1983).
The generation of Alfven waves by magnetic field-aligned electron streams, and the evolution of such streams under the action of the self-generated waves, remains an important question in theoretical radio astronomy. The authors present a simple derivation of a time scale on which a nonlinear Alfven wave packet collapses. This time scale is compared with the linear growth and quasi-linear relaxation time scales for conditions appropriate to an extragalactic radio source. The nonlinear time scale can be comparable to the linear and quasi-linear time scales, which suggests that nonlinear effects may stabilize this instability and permit the propagation of anisotropic electron streams. (17 refs.)

110880 Statistical mechanics of light elements at high pressure. V. Three-dimensional Thomas-Fermi-Dirac theory. J.J.MacFarlane, W.B.Hubbard (Dept. of Planetary Sci., Univ. of Arizona, Tucson, AZ, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.301-10 (1 Sept. 1983).
For pt.IV see ibid., vol.205, no.1, p.295-301 (1976). Presents a new numerical technique for solving the Thomas-Fermi-Dirac equation in three dimensions, for an array of ions obeying periodic boundary conditions. The technique is then used to calculate deviations from ideal mixing for an alloy of hydrogen and helium at zero temperature and high pressures. Results are compared with alternative models which apply perturbation theory to calculation of the electron distribution, based upon the assumption of weak response of the electron gas to the ions. The results indicate that predicted phase separation curves for hydrogen-helium alloys under conditions prevailing in the metallic zones of Jupiter and Saturn are very model dependent. (18 refs.)

110881 Comments on the Planck-Larkin partition function. C.A.Rouse (GA Technologies Inc., San Diego, CA, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.377-9 (1 Sept. 1983).
Several comments are presented regarding the Planck-Larkin partition function (PLPF) and scattering states. It is shown that the major physical problem with the temperature-dependent PLPF is that the effective maximum bound state for hydrogen predicted in this theory is considerably less than the maximum hydrogen lines observed in the solar photosphere and chromosphere. Regarding the partial compensation of bound states in an internal electron partition function by continuum states, it is noted that the time-averaged terms of a sum over states are all positive; hence, compensation is not possible. (26 refs.)

110882 Blast waves with cosmic-ray pressure. R.A.Chevalier (Dept. of Astron., Univ. of Virginia, Charlottesville, VA, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.765-72 (15 Sept. 1983).
Investigates the effect of efficient cosmic-ray acceleration on the structure of blast waves and of driven waves created by supernova explosions. The solutions for the structures are used to predict the pion-decay γ-ray fluxes from supernovae and supernova remnants. (20 refs.)

110883 Effect of molecules and grains on Rosseland mean opacities. D.R.Alexander (Dept. of Phys., Wichita State Univ., Wichita, KS, USA), H.R.Johnson, R.L.Rypma.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.773-80 (15 Sept. 1983).
Rosseland mean opacities, which include the effects of molecules and grains, have been computed down to 630K. Molecular effects have been computed with the opacity sampling method wherever possible. A detailed treatment of the condensation of and absorption due to grains has also been included for magnesium silicates and iron. The contributions of molecules (between 3000K and 1500K) and grains (below 1600K) are several orders of magnitude above the Rosseland mean opacity computed without them. The overall metal abundance and the C/O ratio can also dramatically affect the total opacity. (32 refs.)

110884 Viscous drag on an accretion disk due to an embedded stellar system. J.P.Ostriker (Princeton Univ. Obs., Princeton, NJ, USA).
Astrophys. J. (USA), vol.273, no.1, pt.1, p.99-104 (1 Oct. 1983).
If a gaseous disk, such as an accretion disk, is embedded in a more massive stellar system, then interactions between the stars and the gas produce a torque removing angular momentum from the disk. The drag time at any radius is always of the order of the relaxation time in the stellar system regardless of the disk properties. A specific calculation is carried out for two cases, the isotropic Bahcall-Wolf $E^{-1/4}$ distribution thought to form about a black hole and the isothermal Maxwellian distribution. The result has interesting implications for active galactic nuclei if these involve, as is sometimes thought, accretion of gas onto central black holes, for it provides a mechanism for removing angular momentum from the disk. A speculative scenario is also presented whereby a dense stellar system might simulate many of the properties of an active galactic nucleus without invoking a central black hole. (26 refs.)

110885 An approximate analytical solution for self-similar flow behind a radiation driven shockwave. J.B.Singh (Dept. of Maths., SGR Post-Graduate Coll., Dobhi, Jaunpur, India).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.123-6 (July 1983).
An approximate analytical solution for a self-similar flow behind a radiation driven shockwave is obtained using the Laumbach and Probstein's (1969) method in non-uniform atmosphere at rest. (6 refs.)

110886 A self-similar flow behind an exponential shock with radiative heat flux. II. J.B.Singh, P.R.Vishwakarma (Dept. of Math., SGR Postgraduate Coll., Dobhi, Jaunpur, India).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.127-32 (July 1983).
Self-similar solutions, for one-demensional unsteady flow of a perfect gas behind an exponential shock propagating into a uniform atmosphere, are obtained, taking radiation flux into consideration. The total energy of the wave is variable. (5 refs.)

110887 Exact solutions of the equation of radiative transfer in a line in the case of partial frequency redistribution. D.I.Nagirner (Leningrad State Univ., Leningrad, USSR).
Astrophysics (USA), vol.18, no.4, p.348-53 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.608-15 (Oct.-Dec. 1982).
A study is made of multiple scattering of radiation in a spectral line broadened solely by the motion of atoms in an infinite medium in the presence of homogeneous and isotropic sources. Continuum absorption is ignored. An exact expression is found for the radiation intensity for arbitrary frequency dependence of the power of the primary sources. This yields the intensity in the case of time-dependent sources radiating in the line center if the velocity of light is infinite. The asymptotic behavior of the intensity in the line wing and at large times is studied. (18 refs.)

110888 Gravitational lenses with angular momentum. J.Ibanez (Dept. de Fisica, Univ. del Pais Vasco, San Sebastian, Spain).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.175-80 (Aug. 1983).
The bending angle of a photon passing near a rotating body is used to show the influence of angular momentum in a gravitational lens. The expressions are evaluated for spherical and spheroidal deflectors. (10 refs.)

110889 Hydrogen line broadening in the presence of a magnetic field with the unified classical path theory. G.Mathys (Inst. d'Astrophys., Cointe-Ougree, Belgium).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.13-22 (Aug. 1983).
The expression of hydrogen line profiles in the presence of a magnetic field is derived by the unified classical straight line path theory. Lower state interactions are taken into account. Time ordering effects and ion-radiator motion are neglected. The simplifying cases of no lower state interacion and of the line wings are described. Results of preliminary calculations, dealing with Lyman-α (thus without lower state interaction), are presented and compared with results obtained previously with the impact theory and with the unified theory results in the absence of a magnetic field. (21 refs.)

110890 The gravitational potential due to uniform disks and rings. H.Lass (Jet Propulsion Lab., Pasadena, CA, USA), L.Blitzer.
Celestial Mech. (Netherlands), vol.30, no.3, p.225-8 (July 1983).
The gravitational potential due to thin uniform disks and rings is obtained in closed form in terms of complete elliptic integrals. (1 ref.)

110891 Constraints on light particles from stellar evolution. J.Ellis, K.A.Olive (CERN, Geneva, Switzerland).
Nucl. Phys. B, Part. Phys. (Netherlands), vol.B223, no.1, p.252-68 (15 Aug. 1983).
The authors examine the constraints imposed on the numbers and interactions of light particles by our understanding of the late stages of stellar evolution, including red giants, carbon-burning stars and cooling neutron stars. They show that these astrophysical considerations restrict the number of neutrino types to be less than $10^{+2\pm1}$. This result complements the standard constraint from cosmological nucleosynthesis, which was unable to exclude numbers of neutrinos between a few thousand and the best particle physics limit of order 10^5. They also investigate the constraints on supersymmetric theories with a light photino and gravitino, finding that the supersymmetry breaking scale parameter $f>O(100\ \mathrm{GeV})$ and the selectron masses are >20 to 40 GeV. Finally, they study energy-loss rates by majoron and invisible axion emission. (29 refs.)

110892 The propagation of torsion along flux tubes subject to dynamical nonequilibrium. E.N.Parker (Dept. of Astron. & Astrophys., Univ. of Chicago, Chicago, IL, USA).
Geophys. & Astrophys. Fluid Dyn. (GB), vol.24, no.4, p.245-72 (1983).
The dynamical nonequilibrium of close-packed flux tubes is driven by the torsion in the individual tubes so that, wherever tubes with the same sense of twisting come into contact, there is reconnection of their azimuthal field components. The reconnection consumes the local torsion, causing the propagation of torsional Alfven waves into the region from elsewhere along the tubes. Application of the Sun suggests that the propagation of torsion from below the visible surface up into the corona is an important energy supply to the corona. (38 refs.)

110893 The macroscopic magnetohydrodynamics of inhomogeneously turbulent cosmic plasmas. S.I.Vainshtein, L.L.Kichatinov (Siberian Inst. of Terrestrial Magnetism, Ionosphere & Radio Wave Propagation, Irkutsk, USSR).
Geophys. & Astrophys. Fluid Dyn. (GB), vol.24, no.4, p.273-98 (1983).
Magnetohydrodynamics turbulence at high magnetic Reynolds numbers is considered. The mean field magnetohydrodynamic equations for the rather general case of inhomogeneous turbulence are derived using the Orszag

(1970) scheme. Special attention is paid to nonlinear effects which are brought about by the back reaction of the magnetic field on the motion. The diamagnetic effect which is accompanied in the nonlinear regime by a paramagnetic effect is considered. The nonlinear transport of large-scale field due to density inhomogeneity is discussed. A physical interpretation is presented which clarifies the mechanism of field transport in an inhomogeneously turbulent medium. (19 refs.)

110894 Nonlinear convection in an imposed horizontal magnetic field. W.Arter (Dept. of Appl. Math. & Theoretical Phys., Univ. of Cambridge, Cambridge, England).
Geophys. & Astrophys. Fluid Dyn. (GB), vol.25, no.4, p.259-92 (1983).
Nonlinear two-dimensional magnetoconvection with a Boussinesq fluid driven across the field-lines, is taken as a model for giant-cell convection in the Sun and late-type stars. A series of numerical experiments shows the sensitivity on the horizontal scale of convection to the applied field and to the Rayleigh number R. Overstable oscillations occur in cells as broad as they are deep, but increasing R leads to steady motions of much greater wavelength. Purely geometrical effects can cause oscillation: this work implies that strong horizontal field will in general lead to time-dependent convection. (36 refs.)

110895 Asymptotic solution of the α^2-dynamo problem. D.Sokoloff (Moscow State Univ., Moscow, USSR), A.Shukurov, A.Ruzmaikin.
Geophys. & Astrophys. Fluid Dyn. (GB), vol.25, no.4, p.293-307 (1983).
The turbulent dynamo equation with non-uniform mean helicity is solved in an approximation, which is similar to the quasi-classical approximation of quantum mechanics. The rate of growth of the magnetic field is evaluated and a condition for dynamo action is obtained. The generated magnetic field is concentrated in the vicinity of an extremum of mean helicity, but in general vanishes at the point of extremum itself. The field is asymptotically force-free. The results obtained here clarify the fact, known from numerical calculations, that the threshold values of the dynamo-number for excitation of dipole and quadrupole modes are very close to each other. (11 refs.)

110896 Search for superheavy monopoles in 65 kg of iron magnetic sand with a SQUID fluxmeter. T.Ebisu, T.Watanabe (Dept. of Phys., Kobe Univ., Kobe, Japan).
J. Phys. Soc. Jpn. (Japan), vol.52, no.8, p.2617-19 (Aug. 1983).
A search was carried out for magnetically trapped monopoles in 65 kg of iron sand with a SQUID-search coil 80 mm in diameter, by heating the sample above its Curie point. The authors have found no candidate event compatible with the passage of a single Dirac charge. An upper limit of 1.5×10^{-5} monopoles/g is set for the density of monopoles heavier than 2.5×10^{15} GeV/c^2 in the iron sand of $(6\sim25)\times10^6$ years old. One can estimate the flux of cosmic monopole less than 1.3×10^{-11} cm^{-2} sec^{-1} sr^{-1} according to the age and the density of the sample examined. (12 refs.)

110897 Collective bifurcation of flux sheets in two-dimensional magnetoconvection. M.R.E.Proctor (Dept. of Appl. Maths. & Theoretical Phys., Cambridge, England).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.935-43 (Sept. 1983).
A simple model of the dynamical effect of magnetic flux sheets on two-dimensional magnetoconvection, due to Galloway, Proctor and Weiss (1977, 1978) is used to show that if the flux is sufficiently strong steady states can be attained with the flux distributed unevenly between the cell boundaries. The model helps to elucidate the criterion for this bifurcation and makes possible a study of the interaction of several sheets. The relevance of the results to the solar convection zone is discussed. (8 refs.)

110898 Slow neutron capture origin for ^{180}Ta^m. K.Yokoi, K.Takahashi (Inst. fur Kernphys., Tech. Hochscule Darmstadt, Darmstadt, Germany).
Nature (GB), vol.305, no.5931, p.198-201 (15 Sept. 1983).
Most naturally-occurring heavy isotopes ($A\geq74$) are believed to be synthesized by the slow (s-) and rapid (r-) neutron capture processes, with the rest (some 30 neutron-deficient isotopes including ^{180}Ta) being conventionally classified as p-process elements. The very rare isotope ^{180}Ta (a nuclear isomeric state ^{180}Ta^m with a half-life $\geq3\times10^{13}$ yr) is of particular astrophysical interest because of its uncertain origin. It is shown that a significant amount of ^{180}Ta^m may be produced in the s-process. (36 refs.)

110899 An electron cyclotron maser instability for astrophysical plasmas. H.P.Freund, HH.K.Wong, C.S.Wu, M.J.Xu (Inst. for Phys. Sci. & Technol., Univ. of Maryland, College Park, MD, USA).
Phys. Fluids (USA), vol.26, no.8, p.2263-70 (Aug. 1983).
The electron cyclotron maser instability is analyzed for a plasma which consists of a suprathermal electron component characterized by velocity-space anisotropies in directions both parallel and perpendicular to the ambient magnetic field, as well as a high-density thermal plasma in which $\omega_e\sim\Omega_e$ (where ω_e and Ω_e are the electron plasma and cyclotron frequencies). The complete relativistic resonance condition is used and shown to result in a 'resonance ellipse' in momentum space. The instability is considered for both cold and warm suprathermal electron distributions, and for frequencies $\omega\sim\Omega_e$ in the ordinary mode and $\omega\sim2\Omega_e$ in the fast extraordinary mode. It is shown that the growth rates are comparable for these harmonics over a wide range of parameters which, since they are escape modes of the plasma, can lead to comparable radiation intensities. (21 refs.)

110900 Saving the invisible axion. P.J.Steinhardt (Dept. of Phys., Univ. of Pennsylvania, Philadelphia, PA, USA), M.S.Turner.
Phys. Lett. B (Netherlands), vol.129B, no.1-2, p.51-6 (15 Sept. 1983).
Recently it has been shown that the energy density contributed in the present Universe by coherent oscillations of the invisible axion field corresponds to $\Omega\simeq0.1\ (f_a/10^{12}\ \mathrm{GeV})^{11/9}$ (f_a is the scale of Peccei-Quinn SSB), apparently ruling out $f_a\gtrsim O(10^{13}$ GeV). The authors propose a simple way to avoid this bound: entropy production when the temperature of the Universe is between about 1 GeV and 1 MeV. The entropy might be produced by a first-order phase transition, or the out-of-equilibrium decays of a relic particle species. For $f_a\simeq10^{15}$ GeV, the entropy of the Universe must be increased by a factor of $O(10^2\text{-}10^3)$ to have $\Omega_a\simeq O(1)$. If inflation also occurs at a temperature $\simeq10^{15}$ GeV, then the de Sitter space produced fluctuations in the axion field lead to a Zel'dovich-like spectrum of (isothermal) perturbations in the axion energy density, with amplitude about 10^{-4}. It has recently been argued that in an axion-dominated Universe such a spectrum could lead to the formation of the structure observed in the Universe today. (31 refs.)

110901 Transfer of line radiation: comparison of various approximations. V.V.Ivanov.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.364-7 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
High-accuracy approximate solutions promising to revolutionize calculations of line radiation fields in non-LTE atmospheres are compared with the exact asymptotic solutions given by analytical methods. The standard problem of line formation is used as a working example. (5 refs.)

110902 Collisional-induced dissociation of the molecular hydrogen in rarefied gas. Yu.I.Izotov.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.441-4 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
For the temperatures $10^3\text{-}1.5\times10^4$K and number densities $1\text{-}10^7$ cm^{-3} the rate constant of the reaction $H_2+H\rightarrow H+H+H$ is calculated including all the H_2 vibrational states. It is shown that in a rarefied gas with a density $\leq10^4$ cm^{-3} the main contribution to the dissociation rate comes from the low vibrational states of the H_2 molecule. (15 refs.)

110903 On equilibrium figures for ideal fluids in the form of confocal spheroids rotating with common and different angular velocities. D.Montalvo, F.J.Martinez, J.Cisneros (Univ. Autonoma de San Luis Potosi, San Luis Potosi, Mexico).
Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.4, p.293-300 (March 1983).
For a fluid mass consisting of two confocal spheroids each one with different density, the authors demonstrate, firstly, the non-existence of equilibrium figures if both spheroids rotate with a common angular velocity and, secondly, the existence of equilibrium figures if they rotate with different angular velocities. The fluid is considered incompressible, self-gravitating, free from any external pressure and also each spheroid of the model is homogeneous per se. (4 refs.)

110904 Turbulence in a self-gravitating gaseous disk. II. Turbulence spectra. S.M.Churilov, I.G.Shukhman (Inst. of Terrestrial Magnetism, Ionosphere, & Radio-Wave Propagation, Acad. of Sci., Irkutsk, USSR).
Sov. Astron. (USA), vol.26, no.6, p.660-5 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR),* vol.59, no.6, p.1093-102 (Nov.-Dec. 1982).
For pt.I see Astron. Zh., vol.58, no.2, p.260-72 (1981); (Sov. Astron., vol.25, no.2, p.147-53, 1981). Two-dimensional turbulence combining Jeans waves with vortical motion is investigated for the case of self-gravitating gaseous disk. Spectra of pure Jeans turbulence in the inertial interval are obtained which correspond to a constant energy flux. Statistical-equilibrium turbulence spectra are derived and analyzed in the general case, where both Jeans waves and vortices are excited. (13 refs.)

110905 Electron-ion and proton-ion collisions in astrophysics. A.Dalgarno (Harvard-Smithsonian Center for Astrophys., Cambridge, MA, USA).
Physics of Ion-Ion and Electron-Ion Collisions. Proceedings of a NATO Advanced Summer Institute, Baddeck, NS, Canada, 13-26 Sept. 1981 (New York, USA: Plenum 1983), p.1-36
Most of the diffuse material in the Universe exists in partly ionized plasmas. In the interstellar medium, the physical conditions range from the cold weakly-ionized dense molecular clouds for which the ionization source is provided by energetic cosmic rays to the hot highly-ionized dilute galactic corona for which the ionization source is provided by thermal electrons, heated by shocks driven by supernova explosions in the disc of the galaxy. Recombination radiation created; following the shock waves produces X-ray and ultraviolet photons whose absorption above the plane also contributes to the coronal heating. In planetary atmospheres, solar radiation is the primary ionization source supplemented at low altitudes by galactic cosmic rays which become relatively more important for the distant planets. (107 refs.)

95.55 ASTRONOMICAL INSTRUMENTS

110906 One-dimensional high time resolution solar observations with the Westerbork Synthesis Radio Telescope. A.Kattenberg (Sonnenborgh Obs., Astron. Inst. at Utrecht, Utrecht, Netherlands), F.Palagi.
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.1-5 (Aug. 1983).
During 1980, in cooperation with the Solar Maximum Mission program, the Westerbork Synthesis Radio Telescope has been used for solar observations with time resolution of 0.1 s. The authors describe the equipment and procedures that were used for these observations. Also, the authors present a summary of the data that were obtained and an overview of the results obtained in the analysis of these data. (8 refs.)

110907 A mercuric iodide detector system for X-ray astronomy I. Design considerations and predictions of background and sensitivity. G.R.Ricker, J.V.Vallerga, D.R.Wood (Dept. of Phys., MIT, Cambridge, USA).
Nucl. Instrum. & Methods Phys. Res. (Netherlands), vol.213, no.1, p.133-44 (15 July 1983). (Proceedings of the Fifth International Workshop on Mercuric Iodide Nuclear Radiation Detectors, Jerusalem, Israel, 6-8 June 1982).
This is the first of two papers describing an extremely sensitive astronomical hard X-ray telescope design based on a mercuric iodide (HgI_2) detector shielded by a bismuth germanate ($Bi_4Ge_3O_{12}$) scintillator. In a version suitable for a Spacelab mission, this shielded detector is located at the focus of a pyrolytic graphite or lithium fluoride concentrator (the Hard X-ray Diffraction Telescope, or HXDT). The background counting rate of the mercuric iodide detector at balloon altitudes is calculated using a Monte Carlo simulation of the detector assembly in the radiation environment at 40 km above sea level. (22 refs.)

110908 A mercuric iodide detector system for X-ray astronomy. II. Results from flight tests of a balloon borne instrument. J.V.Vallerga, R.K.Vanderspek, G.R.Ricker (Dept. of Phys., MIT, Cambridge, MA, USA).
Nucl. Instrum. & Methods Phys. Res. (Netherlands), vol.213, no.1, p.145-54 (15 July 1983). (Proceedings of the Fifth International Workshop on Mercuric Iodide Nuclear Radiation Detectors, Jerusalem, Israel, 6-8 June 1982).
For pt.I see ibid., vol.213, no.1, p.133-44 (1983). To establish the expected sensitivity of a new hard X-ray telescope design, described by Ricker et al. (1983), an experiment was conducted to measure the background counting rate at balloon altitudes (40 km) of mercuric iodide, a room temperature solid state X-ray detector. The prototype detector consisted of two thin mercuric iodide (HgI_2) detectors surrounded by a large bismuth germanate ($Bi_4Ge_3O_{12}$) scintillator operated in anticoincidence. The bismuth germanate shield vetoed most of the background counting rate induced by atmospheric gamma-rays, neutrons and cosmic rays. A balloon-borne gondola containing a prototype detector assembly was designed, constructed and flown twice in the spring of 1982 from Palestine, Texas. The second flight of this instrument established a differential background counting rate of $4.2 \pm 0.7 \times 10^{-5}$ counts/s cm^2 keV over the energy range of 40-80 keV. This measurement was within 50% of the predicted value. The measured rate is ~ 5 times lower than previously achieved in shielded NaI/CsI or Ge systems operating in the same energy range. The prediction was based on a Monte Carlo simulation of the detector assembly in the radiation environment at float altitude. Details of the simulation can be found in paper I. (8 refs.)

110909 Near-infrared mapping spectrometer for investigation of Jupiter and its satellites. I.M.Aptaker (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
Proc. SPIE Int. Soc. Opt. Eng. (USA), vol.366, p.96-111 (1983). (Modern Utilization of Infrared Technology VIII, San Diego, CA, USA, 26-27 Aug. 1982).
The Near-Infrared Mapping Spectrometer (NIMS) is one of the science instruments in the Galileo Mission, which will explore Jupiter and its satellites in the early-1990s. The NIMS experiment will map geological units on the surfaces of the Jovian satellites, characterize their mineral content; and for the atmosphere of Jupiter, investigate cloud properties and the spatial and temporal variability of molecular abundances. All the optics are gold-coated reflective and consist of a telescope and a grating spectrometer. The balance of the instrument includes a 17-detector (silicon and indium antimonide) focal plane array, a tuning fork chopper, microprocessor-controlled electronics, and a passive radiative cooler. A wobbling secondary mirror in the telescope provides 20 pixels in one dimension of spatial scanning in a pushbroom mode, with 0.5 mr×0.5 mr instantaneous field of view. The spectral range is 0.7-5.2 μ; resolution is 0.025 μ. NIMS is the first infrared experiment to combine both spatial and spectral mapping capability in one instrument. (no refs.)

110910 Covariance analysis of a charge carrier device processing algorithm for stellar sensors. B.Boxenhorn (Charles Stark Draper Lab. Inc., Cambridge, MA, USA).
J. Guid. Control & Dyn. (USA), vol.6, no.4, p.239-45 (July-Aug. 1983).
This paper addresses the problem of modeling a charge carrier device imager array, develops equations for propagating the signal, and develops equations to propagate the noise. Equations are used for a window processor with a comparator for stellar detection. Finally, a numerical example is presented that shows how the probability of detection varies as a function of the signal-to-noise ratio and charge-transfer inefficiency. Some surprising results are explained. (3 refs.)

110911 Three-element very-long baseline radiointerferometer. L.I.Matveenko, R.Z.Sagdeev, V.I.Kostenko, L.R.Kogan, E.P.Molotov, S.P.Ignatov, A.B.Severnyi, I.G.Moiseev, V.A.Efanov, R.L.Sorochenko, R.M.Martirosyan, A.M.Aslanyan.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.415-20 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
The three-element radiointerferometer Pushchino-Evpatoriya-Simeiz with the 22, 70, and 22 m antennas respectively was put into operation in July 1982. First observations were carried out at the 1.35 cm wavelength. The interferometer enables one to study angular structures with sizes of 2.5 to 85 msec of arc. The maximum sensitivity is 20 mJy at the 250 kHz recording bandwidth and 100 sec integration time. The visibility functions of the Orion-KL and W51M maser sources in a water vapor line are presented. Their angular sizes and brightness temperatures are estimated. (6 refs.)

110912 Diffraction on a segmented telescope mirror. A.V.Lenskii (Kiev State Univ., Kiev Ukrainian SSR).
Sov. Astron. (USA), vol.26, no.6, p.734-5 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1225-8 (Nov.-Dec. 1982).
The possibility of using a composite telescope mirror as a reflection echelon is demonstrated. (4 refs.)

95.65 AUXILIARY AND RECORDING INSTRUMENTS

110913 A microprocessor-controlled multichannel counter for a digital autocorrelator [radioastronomical application]. G.Comoretto (Univ. di Firenze, Firenze, Italy).
J. Phys. E (GB), vol.16, no.9, p.836-9 (Sept. 1983).
A multichannel general purpose counter, composed of 1024×32-bit counters, is presented. The circuit is based on a random access memory, and is microprocessor controlled. The microprocessor structure is also described. This circuit has been developed for a digital autocorrelator for radioastronomical observations. (8 refs.)

110914 Pickering-racine prisms revisited. C.A.Christian, R.Racine (Canada-France-Hawaii Telescope Corp., Kamuela, HI, USA).
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.457-60 (July 1983).
Rediscusses the use of Pickering-Racine prisms for extension of photometric calibration sequences to faint magnitudes. The design philosophy and practical implementation techniques are reviewed. The authors emphasize the specific procedures to be followed during the preparation and execution of an observing program, as well as in the data reduction. Finally, a test of the use of such a device, based on data for the globular cluster NGC 2419, is reviewed. No correlation is found between Δm and magnitude, when photographic magnitudes are compared to those determined from a linear, electronic detector. (12 refs.)

Multi-object spectroscopy with optical fibres .... See Entry 110925

95.70 OTHER INSTRUMENTATION AND TECHNIQUES

(inc. clocks, frequency standards)

110915 A clear-sky detector using reflected artificial light. H.E.Mostert.
J. Br. Astron. Assoc. (GB), vol.93, no.5, p.205-9 (Aug. 1983).
A clear-sky detector is described, based upon the principle of determining when frequency-modulated artificial light is reflected back to the detector by the sky. The operating threshold may be varied to allow for local conditions and the sensitivity required. (3 refs.)

110916 Counting the stars by computer. E.Kibblewhite.
New Sci. (GB), vol.99, no.1371, p.478-82 (18 Aug. 1983).
Lasers and computer control have led to a machine which dramatically speeds up astronomers' analyses of photographs—and has led to new kinds of astronomical objects being identified. Its inventor explains how. (no refs.)

95.75 TECHNIQUES OF OBSERVATION AND REDUCTION

110917 On searches for periodic pulsed emission: the Rayleigh test compared to epoch folding. D.A.Leahy, R.F.Elsner, M.C.Weisskopf (Space Sci. Lab., NASA Marshall Space Flight Center, AL, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.256-8 (1 Sept. 1983).
The Rayleigh test has been recently invoked as a method of searching a time series for periodic pulsations. The authors discuss and compare this technique to epoch folding, a technique which has had widespread use in X-ray astronomy. The authors find that the Rayleigh test provides a more sensitive approach to the search for periodic pulsations when the pulses are sinusoidal or of broad duty cycle, such as those typical of the pulsing X-ray sources.

Epoch folding, on the other hand, is more sensitive to the narrow pulses typical of radio pulsars. (5 refs.)

110918 Analysis methods for results in gamma-ray astronomy. Ti-pei Li, Yu-qian Ma (Inst. of High Energy Phys., Acad. Sinica, Beijing, China).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.317-24 (1 Sept. 1983).
The current procedures for analyzing results of γ-ray astronomy experiments are examined critically. The authors propose two formulae to estimate the significance of positive observations in searching γ-ray sources or lines. The correctness of the formulae are tested by Monte Carlo simulations. (7 refs.)

110919 Speckle interferometry degraded by irregular motion of a scanning telescope mirror. C.Leinert, H.M.Dyck (Max-Planck-Inst. fur Astron., Heidelberg-Konigstuhl, Germany).
Appl. Opt. (USA), vol.22, no.16, p.2403-4 (15 Aug. 1983).
A common feature of IR telescopes is a chopping secondary mirror used to remove thermal background effects. With the secondary operated in a slow-scanning mode, 2-D images of infrared-bright sources can be constructed by incrementing the telescope position in a direction perpendicular to the scan. Not all secondary systems work well enough, however, to produce the desired results and the authors report the results of numerical calculations which confirm that small erratic motions of the secondary result in degraded double-star visibilities of the observed kind. (6 refs.)

110920 Remote sensing by IR heterodyne spectroscopy. T.Kostiuk, M.J.Mumma (NASA Goddard Space Flight Center, Greenbelt, MD, USA).
Appl. Opt. (USA), vol.22, no.17, p.2644-54 (1983). (Topical Meeting on Optical Techniques for Remote Probing of the Atmosphere, Incline Village, NV, USA, 10-12 Jan. 1983).
The use of IR heterodyne spectroscopy for the study of planetary atmospheres is discussed. Infrared heterodyne spectroscopy provides a convenient and sensitive method for measuring the true intensity profiles of atmospheric spectral lines. Application of radiative transfer theory to measured line shapes can then permit the study of molecular abundances, temperatures, total pressures, excitation conditions, and dynamics of the regions of line formation. The theory of formation of atmospheric spectral lines and the retrieval of the information contained in these molecular lines are illustrated. Notable successes of such retrievals from IR heterodyne measurements on Venus, Mars, Jupiter, and Earth are given. A discussion of new developments in IR heterodyne technology is also presented. (62 refs.)

110921 A new method of determining nebular radial velocities from Fabry-Perot interferograms. M.Thonnat (Lab. d'Astron. Spatiale, CNRS, Marseille, France), B.Ruffini, J.Caplan, A.Llebaria.
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.236-40 (Aug. 1983).
Interferograms are digitised with a PDS microphotometer and then analysed automatically to give radial velocity fields. It is concluded that this new method, which works at constant dispersion and which is much more rapid and convenient, is a very satisfactory alternative to the former procedures. (20 refs.)

110922 A method to improve the visibility of time-variable gamma-ray sources in structured background. M.E.Ozel, H.A.Mayer-Hasselwander (Max-Planck-Inst. fur Extraterrestrische Phys., Garching, Munchen, Germany).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.130-5 (Aug. 1983).
For the investigation of time variable gamma-ray sources embedded in a spatially structured background emission, the spatial selection of those gamma-ray events which are probable to increase the observed signal is not a trivial task. A method is presented which allows for the optimum event selection without introducing any statistical trials which could reduce the significance of the result. The method is applied to simulated and observed data to demonstrate its feasibility and merits. (14 refs.)

110923 Determination of effective temperatures for hot stars from integrated fluxes. W.Tobin (Lab. d'Astron. Spatiale, CNRS, Marseille, France).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.168-71 (Aug. 1983).
An analysis is made of the method of determination of effective temperatures for early-type stars from monochromatic and integrated fluxes. The essence of the method is a comparison of model predictions with the de-reddened ratio (observed monochromatic flux in the visual or infrared)/(observed integrated flux), and solutions may be found graphically without iteration. Likely errors in effective temperature are discussed. (14 refs.)

110924 On the performance of video band complex correlators. P.C.Egau (Dept. of Electrical Engng., Univ. of Nairobi, Nairobi, Kenya).
IEEE Trans. Aerosp. & Electron. Syst. (USA), vol.19, no.3, p.462-6 (May 1983).
The performance data for various correlation schemes for Gaussian signals converted from the intermediate frequency band to the video band are derived and discussed. The folded-band conversion scheme is shown to have significant advantages for continuum observations in radioastronomy. (8 refs.)

110925 Multi-object spectroscopy with optical fibres. F.G.Watson (UK Schmidt Telescope, Coonabarabran, Australia).
J. Br. Astron. Assoc. (GB), vol.93, no.5, p.193-9 (Aug. 1983).
An informal review of fibre-optics spectroscopy is presented. This simple new technique permits a conventional spectrograph to be used in a highly efficient, two-dimensional mode. Details of some existing systems are given, and future plans are outlined. (16 refs.)

95.85 CATALOGUES, ATLASES ETC

110926 New galaxies with ultraviolet excess. IV. M.A.Kazaryan, E.S.Kazaryan (Erevan State Univ., Erevan, USSR).
Astrophysics (USA), vol.18, no.4, p.285-96 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.512-22 (Oct.-Dec. 1982).
For pt.III see Astrofizika, vol.16, no.1, p.17-23 (1980) or Astrophysics, vol.16, no.1, p.7-20 (1980). A fourth list containing 114 new galaxies with ultraviolet excess found by means of the 40″ Schmidt telescope of the Byurakan Observatory with α 1.5° objective prism is given. It is concluded that a stage with an ultraviolet excess is a frequent and long lasting phenomenon in galaxies. (4 refs.)

110927 A catalogue of extragalactic radio source identifications. M.P.Veron-Cetty, P.Veron (European Southern Obs., Garching, Munchen, Germany).
Astron. & Astrophys. Suppl. Ser. (France), vol.53, no.2, p.219-21 (Aug. 1983).
Presents a compilation of all published identifications of extragalactic radio sources and of all radio quiet quasars with known redshift. The catalogue contains 14585 entries for 10173 different sources published in 917 papers. (no refs.)

110928 Meridian observations made with the Carlsberg Automatic Meridian Circle at Brorfelde (Copenhagen University Observatory) 1981-1982. L.Helmer, C.Fabricius, O.H.Einicke (Copenhagen Univ. Obs., Copenhagen, Denmark), C.Thoburn.
Astron. & Astrophys. Suppl. Ser. (France), vol.53, no.2, p.223-45 (Aug. 1983).
The catalogue contains positions and magnitudes for 1577 stars with visual magnitudes brighter than 11.0. The observations were made with the 7-inch circle at Copenhagen University Observatory during the period July 1981 to May 1982. The instrument has been equipped with a photoelectric moving-slit micrometer and a minicomputer to control the entire observing process, making it a fully automated transit circle. The internal mean errors of a single observation are $\epsilon_\alpha \cos\delta=0.0138^s$, $\epsilon_\delta=0.216''$, $\epsilon_m=0.132^m$. The positions are reduced relative to the FK4 system for each night and over the whole meridian, instead of the usual narrow zones. The positions of the FK4 stars used in the least squares solution are also given in the catalogue. (19 refs.)

110929 A catalogue of late-type supergiant stars in the Small Magellanic Cloud. L.Prevot, N.Martin (Obs. de Marseille, Marseille, France), E.Maurice, E.Rebeirot, J.Rousseau.
Astron. & Astrophys. Suppl. Ser. (France), vol.53, no.2, p.255-69 (Aug. 1983).
An objective-prism survey of the Small Magellanic Cloud has been made on IIIaJ plates taken with the 1 m ESO Schmidt telescope. This results in the detection of nearly 200 late K and M supergiant stars. Most of these are new probable members of the SMC which do not appear in previous catalogues. The mean visual absolute magnitude $M_v=-6.0$ agrees with the visual absolute magnitude of Iab-Ib galactic supergiants of spectral types M0 to M4. The fraction of known variable stars found in the catalogue is barely 10%; this is 2.5 times less than the value found for the corresponding stars in the LMC. The catalogue provides accurate 1975 coordinates, finding charts, spectral types, *V*-magnitudes, indications concerning radial velocities when available and designations of the stars in other catalogues. (20 refs.)

110930 An atlas of QSO spectra. B.J.Wilkes (Inst. of Astron., Univ. of Cambridge, Cambridge, England), A.E.Wright, D.L.Jauncey, B.A.Peterson.
Proc. Astron. Soc. Aust. (Australia), vol.5, no.1, p.2-83 (1983).
Presents low-dispersion optical spectra of 295 QSO candidates. (36 refs.)

110931 A catalogue of major metre-wavelength solar events recorded by the Dapto and Culgoora solar radio observatories (1961-1981). R.D.Robinson, J.M.Tuxford, K.V.Sheridan, R.T.Stewart (Div. of Radiophys., CSIRO, Sydney, Australia).
Proc. Astron. Soc. Aust. (Australia), vol.5, no.1, p.84-113 (1983).
Presents a catalogue of 668 metre-wavelength radio events, based on dynamic spectra obtained by a radio spectrograph. The data are presented in two tables which list respectively the radio spectral data and flare data, and the morphological properties of the radio events. In addition a third table gives supplementary information for all moving Type IV events observed by the Culgoora radioheliograph or the 158 MHz interferometer. (80 refs.)

110932 Radio data on clusters of galaxies from the Culgoora circular array. O.B.Slee, B.C.Siegman (Div. of Radiophys., CSIRO, Sydney, Australia).
Proc. Astron. Soc. Aust. (Australia), vol.5, no.1, p.114-29 (1983).
The authors reports observations at 80 and 160 MHz of radio sources associated with clusters of galaxies. These low-frequency intensity measurements were combined with published higher-frequency flux data to obtain accurate radio spectra. In addition the 160 MHz contour maps for many of the cluster fields were used to find positions and angular sizes for the associated radio sources. (18 refs.)

110933 On the reduction of the Carte du Ciel catalogues. J.Stock, J.Cova S. (Centro de Investigacion de Astron., Merida, Venezuela).
Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.4, p.233-60 (March 1983).
In the hope of retrieving useful positions for proper motion determinations from the Carte du Ciel (CdC) using recently developed block adjustment methods, an area from the Oxford Zone I of the CdC consisting of 24 overlapping plates of relatively homogeneous epoch is reanalized using the original measurements contained in the catalogue. Positions for equinox 1950.0 and epoch 1901.1 are obtained for 2911 stars down to the limiting magnitude of the catalogue using independently both the AGK3 and the FK4 catalogues as reference systems. The results show that positions accurate to 0.3″ may be obtained and that the block adjustment method used is capable of absorbing distortion terms which are a linear function of the coordinates. (10 refs.)

Faint early-type stars in the neighbourhood of the H II region RCW 99 .... See Entry 111194

95.90 OTHER TOPICS IN ASTRONOMY AND ASTROPHYSICS

110934 A reassessment of the high precision megalithic lunar sightlines. II. Foresights and the problem of selection. C.L.N.Ruggles (Univ. Coll. Cardiff, Cardiff, Wales).
Archaeoastronomy (GB), no.5, p.S1-36 (1983).
For pt.I see ibid., no.4, p.S21-S40 (1982). The author presents foresight declinations for 44 putative high precision lunar sightlines. The inherent uncertainties in these declinations due to uncertainties in the exact observing position are discussed. The problem of the selection of foresights from among other possible horizon features is examined, and the analysis of measured declinations within the 'lunar bands' around the mean standstills is reviewed. Finally a statistical reappraisal of the 44 sightlines is presented. (164 refs.)

110935 The 'Torreon' of Machu Picchu as an observatory. D.S.P.Dearborn, R.E.White (Steward Obs., Univ. of Arizona, Tucson, AZ, USA).
Archaeoastronomy (GB), no.5, p.S37-49 (1983).
The authors report the results of field work during 1980 at Machu Picchu and during 1982 at Pisac. The report concentrates on measurements of the Torreon ('Sentry Tower' or 'Semicircular Temple') and on its possible use as an observatory. It is shown that the structure was designed as a precise instrument for fixing the date of the winter (June) solstice and the date of the passage of the Sun through the zenith, and for observing certain constellations. (23 refs.)

110936 Revised surveys of Cork-Kerry stone circles. J.Patrick (Deakin Univ., Geelong, Australia), P.R.Freeman.
Archaeoastronomy (GB), no.5, p.S50-6 (1983).
The authors report new measurements of the orientations of 31 recumbent stone circles in Cork and Kerry. Some discrepancies between these measurements and those of Barber (1973) are discussed. Some evidence is found for astronomical alignments in the direction from the portal stones of the circle to the recumbent stone: of the 31 sites, sixteen point to within 1° of declination of some astronomical event. (10 refs.)

110937 Observation of the Moon in megalithic times. A.Thom, A.S.Thom.
Archaeoastronomy (GB), no.5, p.S57-66 (1983).
The authors determine the declinations for forty megalithic lunar lines, using refined methods of calculation. Histograms of the observed declinations are presented; and it is concluded that the declinations are correlated with six lunar standstills. Correction of the observations for refraction is discussed; there is some evidence from these corrections that temperatures in megalithic times were about 4 F° higher than those at the present day. (no refs.)

110938 Adventure into space. E.M.Burbridge (Center for Astrophys. & Space Sci., Univ. of California, San Diego, CA, USA).
Science (USA), vol.221, no.4609, p.421-7 (29 July 1983).
Gives a very general discussion of the exploration of the Solar System with space vehicles. The author also discusses observations of extraSolar System objects. (35 refs.)

96.00 SOLAR SYSTEM

96.10 GENERAL, SOLAR NEBULA, AND COSMOGONY

110939 **^{182}Hf chronometer for the early Solar System.** E.B.Norman (Nuclear Phys. Lab., Univ. of Washington, Seattle, WA, USA), D.N.Schramm.
Nature (GB), vol.304, no.5926, p.515-17 (11 Aug. 1983).
Proposes here that ^{182}Hf ($t_{1/2}=9\times10^6$ yr) can resolve the question of whether heavy-element non-actinide nucleosynthesis occurred during a ^{26}Al-producing event. The answer to this question will help to clarify the chronology of the formation of the Solar System and will help to determine the astrophysical sites of heavy-element nucleosynthesis. (27 refs.)

110940 **Cosmogonical implications of elemental and isotopic abundances in atmospheres of the giant planets.** D.Gautier (Lab. d'Astron. Infrarouge, Obs. de Paris, Meudon, France), T.Owen.
Nature (GB), vol.304, no.5928, p.691-4 (25 Aug. 1983).
Current knowledge of element abundances and isotope ratios in the atmospheres of the major planets is reviewed. The observed enhancement of C/H compared with the solar value favours models for the origin of these bodies that invoke the accretion and degassing of an ice-rock core followed by the accumulation of a solar composition envelope. Titan may represent an example of a core-forming planetesimal. Observations of D/H and other isotope ratios must be accommodated by these models in ways that are not yet completely clear. Some additional tests are suggested. (46 refs.)

110941 **Progress toward the origin of the solar system.** S.J.Weidenschilling (Planetary Sci. Inst., Tucson, AZ, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.206-13 (March 1983).
Reviews research published from 1979 through mid-1982. Its emphasis is on physical/dynamical processes that produced the various bodies in the solar system in approximately their present numbers, orbits, compositions and masses. Chemical evidence concerning the state of the solar nebula and planetary accretion is included. (188 refs.)

The Adhi Kot breccia and implications for the origin of chondrules and silica-rich clasts in enstatite chondrites ....See Entry 111000

96.20 MOON

110942 **Petrology and chemistry of two 'large' granite clasts from the Moon.** P.H.Warren, G.J.Taylor, K.Keil (Dept. of Geology, Univ. of New Mexico, Albuquerque, NM, USA), D.N.Shirley, J.T.Wasson.
Earth & Planet. Sci. Lett. (Netherlands), vol.64, no.2, p.175-85 (Aug. 1983).
Reports the discovery and analysis of Apollo-14 breccias 14321 and 14303, two pristine lunar granite clasts, 10-100 times larger than any previously described. The origin of this rare but important rock type is also discussed. (46 refs.)

110943 **Paleomagnetism of the Moon and meteorites.** L.L.Hood (Lunar & Planetary Lab., Univ. of Arizona, Tucson, AZ, USA), S.M.Cisowski.
Rev. Geophys. & Space Phys. (USA), vol.21, no.3, p.676-84 (April 1983).
Discusses chondrites, achondrites, lunar palaeomagnetism, returned samples and discusses orbital analyses. (60 refs.)

DE 102: a numerically integrated ephemeris of the Moon and planets spanning forty-four centuries ....See Entry 110863

96.30 PLANETS AND SATELLITES

(exc. the Moon; for celestial mechanics, see 95.10; for Earth as an astronomical body, see 91. Geophysics)

110944 **Planetary science: 1979-1982.** S.W.Squyres (NASA Ames Res. Center, Moffett Field, CA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.139-42 (March 1983).
Reviews studies of the global topography of Venus, and the analysis of data on Jupiter, Amalthea, Io, Europa, Ganymede, Callisto, Saturn, Mimas, Enceladus, Tethys, Dione, Rhea, Titan, Hyperion, Iapetus, and Phoebe. Among the discoveries are continent-sized landforms on Venus, a ring encircling Jupiter, the most volcanically active surface in the solar system on Io, hitherto unknown forms of global tectonism on icy Europa, Ganymede, and Enceladus, and intricate structure within Saturn's rings. Along with the spectacular growth in knowledge stemming from spacecraft exploration, major advances have also been made in telescopic observations of bodies not yet visited by spacecraft, radar observations of a variety of objects, and theoretical studies of the evolution of both individual bodies and the solar system as a whole. (33 refs.)

110945 **Planetary atmospheres.** R.Beebe (Dept. of Astron., New Mexico State Univ., Las Cruces,NM, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.143-51 (March 1983).
The period from 1979 to 1982 has been characterized by extensive exploration of the Solar System. Pioneer and Voyager missions to Venus, Jupiter, and Saturn combined with ongoing analysis and data collection from the Viking-Mars mission have contributed greatly to the understanding of planetary atmospheres. The review considers bodies in order of increasing distance from the Sun: Venus, Mars, Jupiter, Saturn, Titan, Uranus, Neptune, and Pluto. (254 refs.)

110946 **The geology of the terrestrial planets.** M.H.Carr (US Geological Survey, Menlo Park, CA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.160-72 (March 1983).
Reviews photogeology of Mercury, Venus, the Moon, and Mars during the 1979-82 period. (282 refs.)

110947 **Planetary ring systems.** J.Cuzzi (NASA Ames Res. Center, Moffett Field, CA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.173-86 (March 1983).
Review studies of the rings of Saturn, Jupiter and Uranus and theoretical developments during the period 1979-82. (304 refs.)

110948 **Planetary radar astronomy.** S.J.Ostro (Dept. of Astron., Cornell Univ., Ithaca, NY, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.186-96 (March 1983).
This review of the 1979-82 period begins with a brief synopsis of radar definitions and technical terminology, and then summarizes results for individual targets. (104 refs.)

110949 **Solar-planetary relationships: magnetospheric physics.** D.P.Stern (Planetary Magnetospheres Branch, Goddard Space Flight Center, Greenbelt, MD, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.361-2 (March 1983).
The quadrennium 1979-82 witnessed notable advances in magnetospheric and interplanetary physics, and demonstrated some major trends. Examples of both are listed, followed by an evaluation of the state of the discipline and of its future. (5 refs.)

110950 **Plasma waves in planetary magnetospheres.** R.R.Anderson (Dept. of Phys. & Astron., Univ. of Iowa, Iowa City, IA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.474-94 (March 1983).
Concentrates on US research on plasma waves above the ULF-ELF range within planetary magnetospheres during the 1979-82 quadrennium. (514 refs.)

96.30E Venus

110951 **Solar related waves in the Venusian atmosphere from the cloud tops to 100 km.** L.S.Elson (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
J. Atmos. Sci. (USA), vol.40, no.6, p.1535-51 (June 1983).
A diagnostic, quasi-linear model has been developed which uses observed solar-related temperatures and a specified zonal mean circulation and thermal structure to find the solar-related circulation above the clouds of Venus. Because there are no observations of the mean circulation above the clouds, it has been calculated using an independent model. Although the model-derived, solar-related circulation depends on the mean flow to a much greater degree than is the case for terrestrial tides, and although there is uncertainty in this mean flow, several important conclusions have been drawn concerning the solar-related circulation and thermal structure. (24 refs.)

110952 **Maya observations of very long periods of Venus.** S.C.McCluskey (West Virginia Univ., Morgantown, WV, USA).
J. Hist. Astron. (GB), vol.14, pt.2, p.92-101 (June 1983).
Points out some heretofore unnoticed periods in the Venus Almanac of Codex Dresden and other sources that suggest a connection between Maya observational practices and the precision and predictive techniques found in the Venus Almanac. (18 refs.)

110953 **Rotation of Venus's polar dipole.** J.T.Schofield (Dept. of Atmospheric Phys., Univ. of Oxford, Oxford, England), D.J.Diner.
Nature (GB), vol.305, no.5930, p.116-19 (8 Sept. 1983).
The Venusian polar dipoles are long-lived, elongated, warm features seen in images of thermal esmission from the polar cloud tops of the planet. They are almost 4000 km across, are centred close to the pole, and appear to rotate with a period of ~3 days retrograde. The northern hemisphere dipole was first identified as such by the Orbiter Infrared Radiometer (OIR) on the Pioneer Venus Orbiter (PVO). In this study the authors use OIR images at 11.5 μm to investigate its detailed rotation. Its rotation rate is observed to change steadily over the 72-day data set, and there is some evidence for oscillatory variations superimposed on this trend. (24 refs.)

110954 **Aeronomy of the inner planets.** T.E.Cravens, A.F.Nagy (Space Phys. Res. Lab., Univ. of Michigan, Ann Arbor, MI, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.263-73 (March 1983).
Progress concerning the thermospheres of Venus and Mars is reviewed. A dramatic advance in the understanding of the upper atmosphere and ionosphere of Venus was primarily due to the large amount of data generated by the Pioneer Venus mission. Progress on Mars has been rather modest and has stemmed from theoretical modeling efforts related to the 1976 Viking observations. This report covers the following topics: the thermosphere and ionosphere of Mars, the thermosphere of Venus, some aspects of the solar wind-ionosphere interaction of Venus, the dayside ionosphere of Venus including both composition and energetics, and the nightside ionosphere of Venus. (159 refs.)

Planetary lightning: Earth, Jupiter, and Venus ....See Entry 110595

96.30G Mars

110955 **A theoretical study of small amplitude waves in the Martian lower atmosphere and a comparison made with those on Earth.** A.M.Gadian (Dept. of Maths., Teesside Polytech., Middlesbrough, England), J.S.A.Green.
Ann. Geophys. (France), vol.1, no.3, p.239-43 (May-June 1983).
A linearised study of waves in the Martian atmosphere reveals much similarity with those on Earth. For motion independent of the meridional direction, approximations can be made from the exact solutions and these can be regarded as a useful guide to the relevance and importance of the waves in the Martian atmosphere. The authors distinguish between acoustic waves, including Lamb Waves, inertial gravity, baroclinic and Rossby waves. The beta effect and Newtonian radiative damping will be included for these longer perturbations. (3 refs.)

Aeronomy of the inner planets ....See Entry 110954

96.30H Asteroids

110956 **1983 RD.** C.Shoemaker, E.Shoemaker, R.S.Dunbar, E.Helin, A.C.Gilmore, B.G.Marsden.
I.A.U. Circ. (USA), no.3865, 1 pp. (16 Sept. 1983).
Precise positions are reported for the period 1983 September 7 to 15. Improved orbital elements are given, together with an ephemeris for the period 1983 September 13 to 17, at one-day intervals. (no refs.)

110957 1983 RD. B.G.Marsden, A.W.Harris, R.L.Millis.
I.A.U. Circ. (USA), no.3866, 1 pp. (16 Sept. 1983).
Presents an ephemeris for the period 1983 September 17 to October 3 at one-day intervals, and for October 8 to December 2 at five-day intervals. In addition UBV photometry is reported for 1983 September 13 and 14; these observations are consistent with a rotation period of about 2.5 or about 5 hours. (1 ref.)

110958 Asteroids and comets. C.R.Chapman (Planetary Sci. Inst., Tucson, AZ, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.196-206 (March 1983).
Reviews progress in the study of asteroids, Earth-approaching objects, and comets in the 1979-82 period. (127 refs.)

110959 A qualitative investigation of the motion of asteroids of the Hecuba type. I.A.Gerasimov (P.K. Shternberg State Astron. Inst., Moscow, USSR).
Sov. Astron. (USA), vol.26, no.6, p.715-20 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1190-9 (Nov.-Dec. 1982).
The Delaunay-Hill averaging scheme is applied to the plane, circular, restricted three-body problem with 2:1 commensurability of mean motions. A qualitative investigation is made for the case when the first four terms are retained in the perturbation function. Five types of phase trajectories are found. The stability of singular solutions is analyzed. (14 refs.)

On the determination of absolute right ascensions and declinations of groups of stars using minor planets ....See Entry 110864

96.30K Jupiter

110960 Magnetic drifts at Io: depletion of 10-MeV electrons at Voyager 1 encounter due to a forbidden zone. B.E.Goldstein (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA), W.-H.Ip.
J. Geophys. Res. (USA), vol.88, no.A8, p.6137-42 (1 Aug. 1983).
The possibility that the partial dropout of the 10-MeV electrons observed at Voyager 1 encounter with Io might be explained by a forbidden zone is investigated. Because the convection velocity in the vicinity of Io decreases, grad B drifts of energetic electrons opposing the convection result in a forbidden region around Io. It is found that the location and magnitude of the 10-MeV electron depletion calculated on this basis agrees well with the location found by mapping along draped field lines from the Voyager trajectory to the location of Io. The depletion of 10-MeV electrons thus should not be construed as evidence for a local dipole magnetic field at Io. If the forbidden zone explanation for the 10-MeV dropout observed by Voyager is correct, then no electrons in this energy range would be lost to the surface of Io and there should not be a wake extending behind Io in which electrons of energies 10 MeV are depleted. (19 refs.)

110961 Electron precipitation and related aeronomy of the Jovian thermosphere and ionosphere. J.H.Waite,Jr. (Space Sci. Lab., NASA Marshall Space Flight Center, Huntsville, AL, USA), T.E.Cravens, J.Kozyra, A.F.Nagy, S.K.Atreya, R.H.Chen.
J. Geophys. Res. (USA), vol.88, no.A8, p.6143-63 (1 Aug. 1983).
Voyager ultraviolet spectrometer (UVS) measurements provided the first unassailable evidence for particle precipitation in the Jovian atmosphere. Strong emissions at high latitudes indicate particle precipitation energy fluxes of about 10 ergs cm^{-2} s^{-1}. Dayglow emissions at mid and low latitudes may indicate additional particle precipitation fluxes on the order of 0.3 ergs cm^{-2} s^{-1} at all latitudes. Such particle precipitation can have significant aeronomical effects on the Jovian thermosphere and ionosphere. A one-dimensional theoretical model is used to study these effects for the case of electron precipitation. Diffusion equations are solved for all the major neutral species and for H^+, and photochemical solutions are given for the short lived ions. Calculations of the energy deposition rate and neutral temperature are performed. (80 refs.)

110962 The source location of certain Jovian decametric radio emissions. W.Calvert (Dept. of Phys. & Astron., Univ. of Iowa, Iowa City, IA, USA).
J. Geophys. Res. (USA), vol.88, no.A8, p.6165-70 (1 Aug. 1983).
New evidence supporting the widely accepted concept that certain of the Jovian decametric radio waves originate as northern hemisphere extraordinary mode cyclotron emissions (possibly from the Io flux tube) has been found in the Voyager radio observations. Shortly after the closest approach to Jupiter, the wave signals received by Voyager 1 near 10 MHz exhibited cusps in the fringe pattern which is attributed to Faraday rotation in the Io plasma torus. The diminished Faraday rotation indicated by these cusps implies that the wave path had become perpendicular to the magnetic field in the torus. At nearly the same time, the wave polarization near 1 MHz (where Faraday rotation is absent) exhibited a sudden reversal of its rotation sense, indicating that the wave path for those frequencies had also become perpendicular to the magnetic field at the spacecraft. For these two events it was possible to project the wave paths back toward Jupiter and determine to some extent where the waves originated. (24 refs.)

110963 Terrestrial versus Jovian VLF chorus; a comparative study. U.S.Inan, R.A.Helliwell (Space, Telecommunications & Radiosci. Lab., Stanford Univ., CA, USA), W.S.Kurth.
J. Geophys. Res. (USA), vol.88, no.A8, p.6171-80 (1 Aug. 1983).
The relevant parameters of the magnetospheres of Jupiter and Earth are studied from the point of view of wave-particle resonant interactions that are believed to be responsible for the generation of VLF chorus emissions observed on Voyager-1. Using existing models of the cold and energetic plasma distributions in the Jovian magnetosphere, expressions for the wave-particle interaction length (L_I) and the nonlinearity parameter (ρ) are derived. Values of these parameters are compared with those computed for the Earth's magnetosphere. It is found that the typical interaction lengths are at least 2-5 times larger in the Jovian than in the terrestrial magnetosphere. Also, the wave intensity necessary to reach the threshold of nonlinearity in the Jovian magnetosphere was found to be up to 5-100 times lower. (32 refs.)

110964 A two-stage mechanism for escape of Na and K from Io. M.E.Summers, Y.L.Yung (Div. of Geological & Planetary Sci., California Inst. of Technol., Pasadena, CA, USA), P.K.Haff.
Nature (GB), vol.304, no.5928, p.710-12 (25 Aug. 1983).
It is generally accepted that Io is the source of S, O, Na and K which, after ionization, form the constituents of the Io plasma torus. The authors propose that Na and K escape from Io in two stages. Atoms of Na and K are first sputtered into the atmosphere from the surface by high-energy magnetospheric ions. Atmospheric sputtering by low-energy co-rotating ions then removes these constituents (along with others present) out of Io's gravitational field. It is suggested that the observed Na and K ejection asymmetry is due to preferential sputtering of atmospheric particles on the hemisphere of Io facing Jupiter. (20 refs.)

110965 Outer planets satellites. D.Morrison (Inst. for Astron., Univ. of Hawaii, Honolulu, HI, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.151-9 (March 1983).
Reviews the published literature on the outer planet satellites for 1979-1982. For the Jovian and Saturnian systems it focuses on the Voyager data and their interpretation. Astronomical observations are the source of such data as exist on the satelites of Uranus, Neptune, and Pluto. Because of the large volume of literature published on the satellites it is not possible to assemble a complete bibliography. (111 refs.)

110966 The Jovian magnetosphere. T.J.Birmingham (Lab. for Extraterrestrial Phys., NASA/Goddard Space Flight Center, Greenbelt, MD, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.375-89 (March 1983).
Discusses Jovian fields and plasmas. The author considers the various regions of the Jovian magnetosphere roughly in the order of their distance from the planet. The author first considers briefly the region <4.9 R_J Jovicentric ($R_J=71372$ km is the Jovian radius). Next comes the 4.9-$\sim$8 R_J region, which is dominated by a low energy, heavy ion plasma originating from volcanic activity on the moon Io (5.9 R_J). Next the author considers the large region from 8 R_J to the Jovian magnetopause. Finally the author examines the unique structure of the Jovian magnetosheath and Voyager excursions into the magnetotail at Saturnian distances. (263 refs.)

96.30M Saturn

110967 Secular orbit-orbit resonance between two satellites with nonzero masses. T.Pauwels (Sterrenkundig Obs., Rijksuniv. Gent, Gent, Belgium).
Celestial Mech. (Netherlands), vol.30, no.3, p.229-47 (July 1983).
The Rhea-Titan resonance is studied as a special case of secular orbit-orbit resonances. In earlier studies Rhea's mass has always been neglected. In order to investigate whether this approximation is valid, both masses are taken into account. It is shown that in the Rhea-Titan case the resonance is dominated by the effect of the large difference between the natural precession rates of the lines of apsides of both satellites, leading to approximations containing only one of the masses. For libration about 0 it happens to be Titan's mass, so that neglecting Rhea's mass is valid. Next, the influence of the difference between the natural precession rates on the resonance is examined, and finally it is shown that the libration period is independent of the libration amplitude. (7 refs.)

110968 The microwave opacity of Saturn's rings at wavelengths of 3.6 and 13 cm from Voyager 1 radio occultation. G.L.Tyler, E.A.Marouf, R.A.Simpson, H.A.Zebker, Von R. Eshleman (Center for Radar Astron., Stanford Univ., Stanford, CA, USA).
Icarus (USA), vol.54, no.2, p.160-88 (May 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
Radio occultation observations of Saturn's rings with Voyager 1 provide independent measurements of the complex (amplitude and phase) microwave extinction and the near-forward scattering cross section of the rings at wavelengths of 3.6 and 13 cm. The ring opening was 5.9°. The normal microwave opacities, $\tau[3.6]$ and $\tau[13]$, provide a measure of the total cross-sectional area of particles larger than about 1 and 4 cm radius, respectively. The data for various rings and the Cassini Division are discussed. (26 refs.)

110969 Particle size distributions in Saturn's rings from Voyager 1 radio occultation. E.A.Marouf, G.L.Tyler, H.A.Zebker, R.A.Simpson, Von R. Eshleman (Center for Radar Astron., Stanford Univ., Stanford, CA, USA).
Icarus (USA), vol.54, no.2, p.189-211 (May 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
Observations of microwave opacity $\tau[\lambda]$ and near forward scatter from Saturn's rings at wavelengths λ of 3.6 and 13 cm from the Voyager 1 ring occultation experiment contain information regarding ring particle sizes in the range of about $a=0.01$ to 15 m radius. The opacity measurements $\tau[3.6]$ and $\tau[13]$ are sufficient to constrain the scale factor $n(a_0)$ and index q of a power law incremental size distribution $n(a)=n(a_0)[a_0/a]^q$, assuming known minimum and maximum sizes and a many-particle-thick model. Forward scatter at 3.6 cm is used to solve for a general distribution over the radius range $1\lesssim a\lesssim 15$ m. Distributions $n(a)$ valid over $0.01\lesssim a\lesssim 15$ m are obtained. Mass distributions are computed directly from $n(a)$. Such distributions are obtained for four features in the ring system centered at 1.35, 1.51, 2.01, and 2.12 Saturn radii (R_s). (51 refs.)

110970 W-shaped occultation signatures: inference of entwined particle orbits in charged planetary ringlets. Von R. Eshleman, J.V.Breakwell, G.L.Tyler, E.A.Marouf (Stanford Univ., Stanford, CA, USA).
Icarus (USA), vol.54, no.2, p.212-26 (May 1983).
Observed W-shaped occultation signatures of certain narrow ringlets in the ring systems of Saturn and Uranus imply a concentration of material near their inner and outer radial edges. A model is proposed where edge bunching is a natural consequence of particles in entwined elliptical orbits, with the same particles alternately defining both edges. While such orbits cross over in radius, collisions would not occur if they have small inclinations, the same fixed argument of periapse, and other parameters whereby the particles would 'fly in formation' along compressed helical paths relative to the core of the ringlet, which is taken to be a circle in the equatorial plane. For this model to match to observed ring thickness and ringlet widths, orbit inclinations must be much smaller than their eccentricities, which themselves would be very small compared to unity. Stabilization against collapse due to gravitational perturbations is discussed. (16 refs.)

110971 The evolution of spokes in Saturn's B ring. E.Grun, G.E.Morfill, R.J.Terrile, T.V.Johnson, G.Schwehm (Lunar & Planetary Inst., Houston, TX, USA).
Icarus (USA), vol.54, no.2, p.227-52 (May 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
The optical appearance of spokes is studied in high resolution ($\lesssim$200 km/lp) images obtained by Voyager 2. Spokes are classified into three categories. Several narrow spokes were observed during formation along radial lines in the sunlit portion of the B-ring. The formation time is discussed. The rate of spoke formation is highest at the morning ansa outside Saturn's shadow. Several spokes are found where one edge revolves with Keplerian speed whereas the other edge stays radial. Recurrent spoke patterns are observed at the period of Saturn's rotation. From edge-on views of the ring system, an upper limit for the height of spokes is derived. (24 refs.)

110972 Collisional interactions of ring particles: the ballistic transport process. W.-H.Ip (Max-Planck-Inst. fur Aeronomie, Katlenburg-Lindau, Germany).
Icarus (USA), vol.54, no.2, p.253-62 (May 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
As the erosion rate of the Saturnian rings resulting from meteroid bombardment can be quite significant in the evolutionary history of the ring system, a simple model is constructed to study the relevant dynamics of ballistic transport of the impact ejecta. The combined process of collision with the ring plane particles, with the impact probability related to the optical depth and inelastic rebound from the ring plane until the random motion of the particle is effectively damped, is traced by using the Monte Carlo method. The numerical results indicate that the final distribution of the ejecta depends very much on the initial ejection velocity. (20 refs.)

110973 Formation of fine dust on Saturn's rings as suggested by the presence of spokes. R.Smoluchowski (Dept. of Astron. & Phys., Univ. of Texas, Austin, TX, USA).
Icarus (USA), vol.54, no.2, p.263-6 (May 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
The common interpretation of spokes on the B ring of Saturn is that they are the result of light scattered by electrostatically levitated micrometer- and submicrometer-size dust particles. The origin of this dust in terms of radiation-induced thermal fatigue and collisions between the particles of the ring as well as meteoritic bombardment is investigated. (22 refs.)

110974 Saturn's electrostatic discharges: properties and theoretical considerations. D.R.Evans, J.H.Romig, J.W.Warwick (Radiophys. Inc., Boulder, CO, USA).
Icarus (USA), vol.54, no.2, p.267-79 (May 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
The properties of Saturn's electrostatic discharges (SED) as observed by the Voyager Planetary Radio Astronomy experiment during the two Voyager encounters with Saturn are summarized. Several models for the formation of SED are discussed in light of these observations. The most likely source regions appear to be either the equatorial zone of the planet or the dense part of the B-ring near 1.80 R_s. The strengths and weaknesses of each of these possibilities are examined. A search for an anomaly near 1.80 R_s in the data of other experiments aboard Voyager is carried out. (17 refs.)

110975 Saturn's electrostatic discharges: could lightning be the cause?. J.A.Burns, M.R.Showalter (Cornell Univ., Ithaca, NY, USA), J.N.Cuzzi, R.H.Durisen.
Icarus (USA), vol.54, no.2, p.280-95 (May 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
It is proposed that Saturn's electrostatic discharges (SED) might be generated in the planet's equatorial atmosphere, perhaps as lightning from a storm system. The 10^h10^m periodicity of the signal envelope duplicates that of Saturn's equatorial jet. The rings shield the atmosphere from solar EUV photons, and thereby substantially reduce the local ionospheric cutoff frequency to allow low-frequency SED to leak out. Many of the unusual properties of SED could be explained in terms of changes in the storm system, the relative spacecraft position in the beaming pattern of the source, local refraction of the signal by the highly disturbed ionosphere, the influence of the ring particles on the highest frequency component of SED. A comparison of SED with planetary lightning on other planets is presented. (52 refs.)

110976 Saturn meteorology: a diagnostic assessment of thin-layer configurations for the zonal flow. M.Allison (NASA Goddard Space Flight Center, Inst. for Space Studies, New York, NY, USA), P.H.Stone.
Icarus (USA), vol.54, no.2, p.296-308 (May 1983).
Voyager imaging, infrared, and radio observations for Saturn have been interpreted by Smith et al. (1982) as an indication that the jet streams observed at the cloud tops extend to depths greater than the 10^4-bar level. This analysis assumes a maximum latitudinal temperature contrast of a few percent, a mean atmospheric rotation rate at depth given by Saturn's ratio period, and no variation with latitude of the bottom pressure level for the zonal flow system. These assumptions are not, however, firmly constrained by observation. The diagnostic analysis of plausible alternative configurations for Saturn's atmospheric structure demonstrates that a thin weather layer system cannot be excluded by any of the available observations. A quantitative estimate of the effects of moisture condensation suggests that these might provide the buoyancy contrasts necessary to support a thin-layer flow. (32 refs.)

110977 A determination of the composition of the Saturnian stratosphere using the IUE. P.Winkelstein, J.Caldwell, S.J.Kim (Dept. of Earth & Space Sci., State Univ. of New York, Stony Brook, NY, USA), M.Combes, G.E.Hunt, V.Moore.
Icarus (USA), vol.54, no.2, p.309-18 (May 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
Reduces ultraviolet spectra of Saturn from the IUE satellite to produce a geometric albedo of the planet from 1500 to 3000 Å. By matching computer models to the albedo the authors determine a chemical composition consistent with the data. This model includes C_2H_2 and C_2H_6 with mixing ratios and distributions of $(9 \pm 3) \times 10^{-8}$ in the top 20 mbar of the atmosphere with none below for C_2H_2 and $(6 \pm 1) \times 10^{-6}$ also in the top 20 mbar with none below for C_2H_2 and C_2H_6 distributions and the C_2H_6 mixing ratio are taken directly from the Voyager IRIS model (Courtin et al. 1981). The Voyager IRIS model also includes PH_3, which is not consistent with the UV albedo from 1800 to 2400 Å. The model requires a previously unidentified absorber to explain the albedo near 1600 Å. (35 refs.)

110978 Investigations of the optical properties of Saturn's atmosphere carried out at the Main Astronomical Observatory of the Ukrainian Academy of Sciences. J.M.Dlugach, A.V.Morozhenko, A.P.Vid'Machenko, E.G.Yanovitskij (Main Astron. Obs., Acad. of Sci., Kiev, Ukrainian SSR).
Icarus (USA), vol.54, no.2, p.319-36 (May 1983).
The results of polarimetric, photometric, and spectroscopic investigations of Saturn are given. Polarimetric and photometric investigations shown that in the long wavelength spectral range ($\lambda > 0.5$ μm) spherical particles play the dominant role in the reflected radiation. But for $\lambda < 0.5$ μm, oriented nonspherical particles are revealed in the equatorial region within planetocentric latitudes ±30°. It is suggested that Saturn's rings may be the source of these particles. The brightness coefficient variations are discussed. A number of weak methane absorption bands are measured for the first time, and the ammonia absorption band at $\lambda = 0.648$ μm is present in the low-resolution photoelectric spectrophotometry. The reduction of high-resolution spectrograms confirms the presence of 20 ammonia lines belonging to the band at 0.648 μm. (30 refs.)

110979 Internal gravity waves in Titan's atmosphere observed by Voyager radio occultation. D.P.Hinson, G.L.Tyler (Center for Radar Astron., Stanford Univ., Stanford, CA, USA).
Icarus (USA), vol.54, no.2, p.337-52 (May 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
Dual-wavelength radio observations during the nearly diametric occultation of Voyager 1 by Titan provided 3.6- and 13-cm data on the equatorial neutral atmosphere. Intensity and frequency fluctuations occurred on time scales from about 0.1 to 1.0 sec at both wavelengths whenever the radio path passed within 90 km of the surface, indicating the presence of variations in refractivity on length scales from a few hundred meters to a few kilometers. Strong intensity scintillations were observed for ray periapsis between about 5 and 25 km altitude, while weak scintillations occurred with ray periapsis between the surface and 5 km, and between 25 and 90 km. The observations support a hypothesis of stratospheric gravity waves, possibly driven by a cloud-free convective region in the lowest few kilometers of the atmosphere. (59 refs.)

110980 Hyperion: collisional disruption of a resonant satellite. P.Farinella, A.Milani, A.M.Nobili (Dipartimento di Matematica, Univ. di Pisa, Pisa, Italy), P.Paolicchi, V.Zappala.
Icarus (USA), vol.54, no.2, p.353-60 (May 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
Hyperion is an irregularly shaped object which appears as the likely remnant of a catastrophic collisional evolution. The present Hyperion is probably the 'core' of a disrupted precursor. The numerical experiments performed to explore the region of the phase space surrounding the present orbit show that most fragments ejected with a relative velocity $\gtrsim 0.1$ km/sec rapidly attain chaotic-type orbits, having repeated close encounters with Titan. Ejection velocities of this order of magnitude are expected for a collision at a velocity of ~ 10 km/sec with a projectile-to-target mass ratio of the order of 10^{-3}, similar effects could be produced by less energetic but nearly grazing collisions. (18 refs.)

110981 The inner edge of Saturn's B ring. T.G.Northrop (Lab. for High Energy Astrophys., NASA Goddard Space Flight Center, Greenbelt, MD, USA), J.R.Hill.
J. Geophys. Res. (USA), vol.88, no.A8, p.6102-8 (1 Aug. 1983).
The sharp, 90-km wide transition from an optical depth of 0.2 in the C ring to 1 in the B ring begins at 91970 km from Saturn's center. This radius is found to be almost exactly at the inward stability limit of charged particles launched in the ring plane at the local Kepler velocity, provided these particles have large charge to mass ratio. The zonal harmonic models of Saturn's magnetic field from the Voyager data and the gravitational field model from Pioneer data are essential to get the very close agreement between theory and observation. The theoretical stability limits are 91973 ± 145 km from Voyager 1 magnetic field data and 91991 ± 145 km from Voyager 2 magnetic data. In addition to the magnetic mirror, gravitational, and centrifugal forces, an unknown force must be postulated to produce equilibrium in the ring plane and make the stability calculation meaningful. (12 refs.)

110982 Perturbations in the movement of Saturn's satellites. I.G.Chugunov.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.368-75 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Perturbations in the movement of satellites I-VI due to the influence of Saturn's dynamic oblateness, its rings, the Sun and the mutual influence of satellites on each other are investigated. (9 refs.)

110983 The magnetosphere of Saturn. A.W.Schardt (Lab. of High Energy Astrophys., NASA Goddard Space Flight Center, Greenbelt, MD, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.390-402 (March 1983).
Discusses the magnetic field, solar wind-magnetosphere interactions, Titan-magnetosphere interactions, outer magnetosphere, slot region, inner magnetosphere and the ring region. (98 refs.)

110984 Uranus: variability of the microwave spectrum. G.Gulkis, E.T.Olsen, M.J.Klein (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA), T.J.Thompson.
Science (USA), vol.221, no.4609, p.453-5 (29 July 1983).
Radio astronomical observations of Uranus show that the radio emission spectrum is evolving in time. Ammonia vapor must be depleted in the Uranian atmosphere as Gulkis and his co-workers (1978) previously suggested. Since 1965, ammonia either has been decreasing in time or is a decreasing function of latitude, or both, provided that the radio emission is atmospheric in origin. If Uranus has an observable low-emissivity 'surface', these trends may be reversed. The microwave observations made in 1965, at the time when the spin axis of Uranus was nearly perpendicular to the Sun-Uranus line, are consistent with an atmospheric opacity profile that would be produced by saturated ammonia vapor in a predominantly hydrogen atmosphere. At the present time, when the spin axis of Uranus is nearly aligned with the Sun-Uranus line, the measurements require an opacity that would be produced by saturated water vapor. A large thermal gradient between the pole and equator is ruled out. (13 refs.)

110985 The effect of MHD instabilities on the flaring of cometary plasma tails. M.B.Niedner,Jr., A.I.Ershkovich, J.C.Brandt (Lab. for Astron. & Solar Phys., NASA Goddard Space Flight Center, Greenbelt, MD, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.362-4 (1 Sept. 1983).
The earlier hypersonic pressure balance model of flaring in cometary plasma tails (Ershkovich, Niedner, and Brandt, 1982), is modified to include the effects of magnetohydrodynamic instabilities occurring along the ionopause in the outer-tail regions. The effect of instability is to mix the solar-wind and comet-tail plasmas, increasing the tail magnetic field strength above that calculated from magnetic flux conservation. The earlier model assumed the ionopause to be a tangential discontinuity surface (flux conserving) at all distances, with the result that the magnetic field approached zero in the outer regions of strongly flaring tails. The present model is more realistic. (8 refs.)

110986 Comet Cernis 1983l. S.W.Milbourn.
Br. Astron. Assoc. Circ. (GB), no.637, 1 pp. (12 Sept. 1983).
Reports improved parabolic orbital elements and an ephemeris for the period 1983 September 13 to December 22. (no refs.)

110987 The fleeting comet of mid-May: Comet 1983d (IRAS-Araki-Alcock). J.Sauval.
Ciel & Terre (Belgium), vol.99, no.3, p.85-93 (May-June 1983). In French.
Comments on the May comet (1983d) and shows some photographs obtained especially in Belgium. (no refs.)

110988 Towards an artificial comet. G.Haerendel (Max-Planck-Inst. fur Phys. und Astrophys., Garching, Germany).
ESA J. (Netherlands), vol.7, no.2, p.135-44 (1983).
The AMPTE mission will provide the opportunity to make a large barium release outside the magnetosphere, on its morning flank. The interaction of the barium plasma with the solar-wind flow will resemble in many respects the processes occurring in the ionised coma of a comet. Initially, a diamagnetic cavity about 80 km in radius will be formed, with a compressed magnetic field on the outside in the direction facing the Sun. The downstream side may develop a turbulent wake and be slowly filled with rays emerging from the 'head' of the artificial comet. The rays form as a consequence of a fast trapping of the solar-wind magnetic field in the plasma cloud a few minutes after maximum expansion, due to anomalous transport effects and aided by flute-type macro-instabilities. Heating and acceleration of the ions causes brightening because of the Doppler shifting of the Ba resonance lines out of the bottom of the solar Fraunhofer lines. The visual phenomena may last for several minutes only, with peak magnitudes $m_v \sim +2.5$, but low-light-level TV systems will be able to track the phenomena for 30-60 minutes. (29 refs.)

110989 Comet IRAS (1983k). P.M.Kilmartin, B.G.Marsden.
I.A.U. Circ. (USA), no.3855, 1 pp. (29 Aug. 1983).
Two precise positions are reported for the epoch 1983 August 10. Parabolic orbital elements are given, together with an ephemeris for the period 1983 August 14 to September 23, at ten-day intervals. (no refs.)

110990 Comet Cernis (1983l). M.Hanner, C.E.Spratt.
I.A.U. Circ. (USA), no.3856, 1 pp. (29 Aug. 1983).
Reports the detection during the period 1983 August 9 to 11 of an absorption feature at 2.9 to 3.0 μm. In addition total visual magnitude estimates are reported for the period 1983 August 17 to 21. (no refs.)

110991 Comet Sugano-Saigusa-Fujikawa (1983e). D.Seargent.
I.A.U. Circ. (USA), no.3857, 1 pp. (29 Aug. 1983).
Reports total visual magnitude estimates and coma diameters for the period 1983 June 8 to 16. (no refs.)

110992 Comet IRAS-Araki-Alcock (1983d). V.F.de Assis Neto.
I.A.U. Circ. (USA), no.3857, 1 pp. (29 Aug. 1983).
Reports total visual magnitude estimates and coma diameters for the period 1983 June 7 to 12. (no refs.)

110993 Comet IRAS (1983o). J.Davies, S.F.Green, C.M.Bardwell, A.C.Gilmore, B.G.Marsden.
I.A.U. Circ. (USA), no.3860, 1 pp. (14 Sept. 1983).
Reports the discovery on 1983 July 27 of an 18th-magnitude comet in Carina. Five approximate positions measured by IRAS on 1983 July 27 and September 1 are reported, together with two precise positions for the epoch 1983 September 11. Parabolic orbital elements are given, together with an ephemeris for the period 1983 September 13 to October 13, at five-day intervals. (no refs.)

110994 Comet Shoemaker (1983p). B.Skiff, E.Bowell, R.S.Dunbar, R.E.McCrosky, C.S.Morris, B.G.Marsden.
I.A.U. Circ. (USA), no.3864, 1 pp. (16 Sept. 1983).
Precise positions are reported for the period 1983 September 14 to 16. A total visual magnitude and coma diameter estimate are given for 1983 September 15. Parabolic orbital elements are given, together with an ephemeris for the period 1983 September 3 to November 2, at five-day intervals. (no refs.)

110995 Visual comet photometry. G.S.Keitch.
J. Br. Astron. Assoc. (GB), vol.93, no.5, p.200-4 (Aug. 1983).
Theoretical and practical aspects of visual photometry of the cometary coma are reviewed. Careful analyses of magnitude data are useful for statistical purposes and for future attempts to correlate visual brightness with the production rates and abundances of various cometary species. The photometric parameters are discussed and the practical aspects of obtaining useful m_v estimates are considered with a view to improving and standardizing the data. (18 refs.)

110996 Survey of meteor signal rates observed over a VHF forward-scatter link between Waltair and Dehra Dun. M.Srirama Rao, S.R.Ratnam, D.A.V.Krishna Rao (Dept. of Phys., Andhra Univ., Waltair, India), E.Bhagiratha Rao.
Indian J. Radio & Space Phys., vol.12, no.2, p.50-2 (April 1983).
Diurnal and day-to-day variation in meteor signal rates observed for a period of one year over a VHF forward-scatter link between Waltair and Dehra Dun (a distance of 1533 km) at 48.2 MHz are presented. The diurnal variations of meteor rates are discussed and the results are compared with the meteor wind radar observations at Waltair. (15 refs.)

110997 The effect of the geomagnetic field on the diffusion of meteor trails. S.M.Levitskii, N.Abdrakhmanov, V.P.Timchenko (Kiev State Univ., Kiev, Ukrainian SSR).
Radiophys. & Quantum Electron. (USA), vol.25, no.11, p.883-6 (Nov. 1982). Translation of: *Izv. VUZ Radiofiz. (USSR)*, vol.25, no.11, p.1240-3 (Nov. 1982). [received: Sept. 1983]
It is shown that the nature of the diffusion of meteor trails should depend on the state of the ionosphere. Under nighttime conditions diffusion of underdense trails is mainly of an ambipolar nature, and during the day it is determined by the effect of brief containment within the surrounding ionospheric plasma. Radar observations of the Geminids made under conditions in which the diffusion was ambipolar have shown that when the line of sight coincides with the direction of the minor axis of the ellipsoid formed by the meteor trail in the geomagnetic field, the time constant of attenuation of the radar echo turns out to be greater than for an observation from the direction of the major axis. (16 refs.)

110998 BMS meteor observer's handbook. Vol.II. Telescopic meteor work. 6th edition. R.A.Mackenzie.
London, England: Mackenzie (1983), 10 pp.

110999 Isotopic composition of carbonaceous-chondrite kerogen: evidence for an interstellar origin of organic matter in meteorites. J.F.Kerridge (Inst. of Geophys., Univ. of California, Los Angeles, CA, USA).
Earth & Planet. Sci. Lett. (Netherlands), vol.64, no.2, p.186-200 (Aug. 1983).
Stepwise combustion has revealed systematic patterns of isotopic heterogeneity for C, H and N in the insoluble organic fraction (m-kerogen) from the Orgueil and Murray carbonaceous chondrites indicating a common source. The data cannot be reconciled with a single mass-fractionation process acting upon a single precursor composition. An interstellar, rather than solar nebular, origin for at least some of the meteoritic organic matter is indicated. This has interesting implications for the origin of prebiotic molecules, temperatures in the early solar system, and the isotopic compositions of volatiles accreted by the terrestrial planets. (55 refs.)

111000 The Adhi Kot breccia and implications for the origin of chondrules and silica-rich clasts in enstatite chondrites. A.E.Rubin (Dept. of Mineral Sci., Nat. Museum of Natural History, Smithsonian Instn., Washington, DC, USA).
Earth & Planet. Sci. Lett. (Netherlands), vol.64, no.2, p.201-12 (Aug. 1983).
The Adhi Kot EH4 enstatite chondrite breccia consists of silica-rich clasts, chondrule-rich clasts and matrix. The silica-rich clasts are a new kind of enstatite chondritic material, which contains more cristobalite than enstatite, as well as abundant niningerite and troilite. The bulk atomic Mg/Si ratios of the clasts (0.22-0.40) are much lower than the average for enstatite chondrites (0.79). Kamacite and martensite occur in all three breccia components. The clasts have kamacite-rich rims, and kamacite-rich aggregates occur in the matrix. A unidirectional change in the ambient pS_2/pO_2 ratio in the region of the solar nebula where Adhi Kot agglomerated can explain many of the breccia's petrologic features. (35 refs.)

111001 Experimental investigations of trace element fractionation in iron meteorites. II. The influence of sulfur. J.H.Jones, M.J.Drake (Lunar & Planetary Lab., Univ. of Arizona, Tucson, AZ, USA).
Geochim. & Cosmochim. Acta (GB), vol.47, no.7, p.1199-209 (July 1983).
For pt.I see 9th. Proc. Lunar Planet. Sci. Conf., p.1407-21 (1978). The authors have investigated the partitioning of Ir, Ge, Ga, W, Cr, Au, P, and Ni between solid metal and metallic liquid as a function of temperature and S-concentration of the metallic liquid. Experimentally-determined partition coefficients have been used in conjunction with a fractional crystallization model to reproduce the geochemical behavior of Ni, P, Au and Ir during the magmatic evolution of groups IIAB, IIIAB, IVA and IVB iron meteorites. However, the geochemical behavior of Ge, Ga, W and Cr cannot be reproduced in an internally consistent way. (26 refs.)

111002 Petrogenesis of the Elephant Moraine A79001 meteorite: multiple magma pulses on the shergottite parent body. H.Y.McSween,Jr. (Dept. of Geological Sci., Univ. of Tennessee, Knoxville, TN, USA), E.Jarosewich.
Geochim. & Cosmochim. Acta (GB), vol.47, no.8, p.1501-13 (Aug. 1983).
The EETA 79001 achondrite consists of two distinct igneous lithologies joined along a planar, non-brecciated contact. Both are basaltic rocks composed primarily of pigeonite, augite, and maskelynite, but one contains zoned megacrysts of olivine, orthopyroxene, and chromite that represent disaggregated xenoliths of harzburzite. Both lithologies probably formed from successive volcanic flows or multiple injections of magma into a small, shallow chamber. Many similarities between the two virtually synchronous magmas suggest that they are related. Possible mechanisms to explain their differences are considered. (55 refs.)

111003 Laboratory measurements of D/H ratios in interplanetary dust. E.Zinner, K.D.McKeegan, R.M.Walker (McDonnell Center for Space Sci., Washington Univ., St. Louis, MO, USA).
Nature (GB), vol.305, no.5930, p.119-21 (8 Sept. 1983).
Measurements of noble gas elemental and isotopic abundance patterns have provided evidence that a subset of the particles collected in the upper atmosphere by aircraft are micrometeorites. This 'chondritic' subset is characterized by major and trace element contents within a factor of 2 of cosmic abundances. The authors have found that the deuterium in two such particles is enriched relative to hydrogen by $500\text{-}1100\,^0/_{00}$ when compared with the terrestrial SMOW standard. This result confirms the extraterrestrial origin of the 'chondritic' dust particles and demonstrates that the material preserves an interesting, and potentially unique, isotopic record which may reflect a

memory of processes occurring during (or before) the formation of the solar system. (26 refs.)

96.60 SOLAR PHYSICS

111004 **Observations of high-energy jets in the corona above the quiet Sun, the heating of the corona, and the acceleration of the solar wind.** G.E.Brueckner, J.-D.F.Bartoe (E.O. Hulburt Center for Space Res., Naval Res. Lab., Washington, DC, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.329-48 (1 Sept. 1983).
High spatial resolution observations of the ultraviolet solar spectrum reveal high-energy events in the quiet Sun. They can be classified as turbulent events and jets. The turbulent events show high turbulence confined in small areas while the jets show upward moving material with velocities exceeding the sound velocity in the corona. A single jet carries an energy of 2.5×10^{26} ergs and a mass of 3×10^{11} g at 400 km s^{-1} into the corona at an altitude of 4000-16000 km. Strong shock waves accompanying the jets can heat the corona. A cloud model of the solar wind is proposed where all the kinetic energy of the wind is provided at the solar surface by the high-energy jets. With a birthrate of 24 events per second over the whole Sun, which is within the uncertainties of the observations, the power and mass flux requirements of the corona and the solar wind can be satisfied. (44 refs.)

111005 **Associations between coronal mass ejections and soft X-ray events.** N.R.Sheeley,Jr., R.A.Howard, M.J.Koomen, D.J.Michels (E.O. Hulburt Center for Space Res., Naval Res. Lab., Washington, DC, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.349-54 (1 Sept. 1983).
Studies the association between white light coronal mass ejections (CMEs) and full-disk X-ray events as a function of X-ray duration during the recent years of high sunspot activity (1979-1981). On a time scale of hours, the authors find no duration that separates X-ray events into two distinct classes depending on whether or not they have associated CMEs. Rather, the tendency for long-duration X-ray events to have associated CMEs reflects the fact that, as X-ray duration increases, the differential distribution of events without CMEs falls off faster than the distribution of X-ray events with CMEs. (18 refs.)

111006 **High spatial and temporal resolution observations of the solar Ca II H line.** L.E.Cram (CSIRO Div. of Appl. Phys., Sydney, Australia), L.Dame.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.355-61 (1 Sept. 1983).
A 24 minute time series of photographic Ca II H line spectra made with high spatial and spectral resolution is analyzed to provide data on the range of line profile variations in the quiet Sun. Distribution functions of the line-core intensity and the ratio of emission peak intensities are exhibited and are used to classify the associated line profiles. It is shown that the range of profile variation is significantly larger than that covered by the models A-F of Vernazza, Avrett, and Loeser (1981), especially in relation to the darkest profiles in which no core emission can be detected. Time-resolved spectra are used to show that the 3-minute chromospheric oscillation involves upward-propagating excitation which leads to intense heating in the cell points. (32 refs.)

111007 **A dynamical model of coronal loops.** S.Hinata (Phys. Dept., Auburn Univ., Auburn, AL, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.715-22 (15 Sept. 1983).
It is shown that, for MHD equilibrium configurations in the corona, the plasma transport across the magnetic field drives the plasma motion when the plasma resistivity is taken into account, provided that the equilibrium configurations are not force-free ($J\times B\neq0$), and that the pressure and/or density changes radially from the center of the loop column. (15 refs.)

111008 **H I Lyman-alpha in the Sun: the effects of partial redistribution in the line wings.** D.Roussel-Dupre (Inst. for Astron., Univ. of Hawaii, Honolulu, HI, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.723-38 (15 Sept. 1983).
Presents a form for the Lyman-α redistribution function that is modified to include effects of collisional coupling between different energy states and that can be used in a radiative transfer equation. By separating the source function into its primary components at all heights, the formation of Lyman-α radiation is investigated in detail. Frequencies in the line wing can be mapped back such that the heights of formation for $\Delta\lambda=\pm0.5$-6 Å span the entire solar chromosphere. The usefulness of the Lyman-α wing as an atmospheric probe, however, is limited by long thermalization lengths, a result of almost coherent scattering outside of the Doppler core. (36 refs.)

111009 **A static model of chromospheric heating in solar flares.** P.J.Ricchiazzi, R.C.Canfield (Center for Astrophys. & Space Sci., Univ. of California, San Diego, CA, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.739-55 (15 Sept. 1983).
Models the response of the solar chromosphere to several flare processes: nonthermal electrons, thermal conduction, and coronal pressure. The equations of steady state energy balance, hydrostatic equilibrium, radiative transfer, and atomic statistical equilibrium are solved simultaneously by finite difference methods, using linearization and iteration. It is assumed that the atmospheric response is confined to one dimension by a strong vertical magnetic field. The radiative transfer equation is solved for the most important optically thick transitions of hydrogen, magnesium, and calcium. Radiative loss due to H^-, the EUV and X-ray lines of heavier ions, and free-free bremsstrahlung is included in an optically thin manner. The theoretical atmospheres elucidate the role of various physical processes in establishing the structure of flare chromospheres. (49 refs.)

111010 **Mass and energy balance in the 1973 August 9 flare.** K.P.Dere, J.W.Cook (E.O. Hulburt Center for Space Res., Naval Res. Lab., Washington, DC, USA).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.181-7 (Aug. 1983).
The mass and energy balance of the thermal plasma during the decay phase of the 1973 August 9 solar flare are studied. The analysis is based on observationally determined values for the differential emission measure, density, turbulent and bulk velocities, and physical dimensions. The total particle content and total thermal energy content of the flare plasmas with temperatures above 10^5K and their variation with time are calculated. The particle loss and the energy losses through radiation, conduction, and convection are evaluated. (26 refs.)

111011 **Gamma-ray observational constraints on the origin of the optical continuum emission from the white-light flare of 1980 July 1.** J.M.Ryan, E.L.Chupp, D.J.Forrest, S.M.Matz (Dept. of Phys., Univ. of New Hampshire, Durham, NH, USA), E.Rieger, C.Reppin, G.Kanbach, G.H.Share.
Astrophys. J. Lett. Ed. (USA), vol.272, no.2, pt.1, p.L61-5 (15 Sept. 1983).
Reports the results of γ-ray observations of the white-light flare of 1980 July 1 which started at approximately 1627 UT. The authors conclude that the major white-light emission which occurs in the late phase of the flare could not have been due to heating by electron or ion precipitation. This conclusion is based on the fact that the X-ray and γ-ray flux as measured by the Gamma-Ray Spectrometer on the Solar Maximum Mission (SMM) satellite peaks approximately 1 minute before the maximum of the optical continuum emission. Approximately 73% of the optical continuum emission, representing a spatially and temporally distinct bright point, follows this maximum with little or no X-ray or γ-ray emission in the same period. (20 refs.)

111012 **Influence of turbulent pressure on solar convective modes.** H.M.Antia, S.M.Chitre, D.Narasimha (Tata Inst. of Fundamental Res., Bombay, India).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.865-81 (Sept. 1983).
The stability of linear convective modes in the solar envelope model is investigated by incorporating in a very crude manner the effects of turbulent pressure and eddy transport coefficients calculated in the mixing length approximation. It is demonstrated that for a reasonable choice of the parameters there occur two peaks in the growth rate versus horizontal wavenumber plot which correspond to the observed features associated with granulation and supergranulation. (29 refs.)

111013 **Solar oscillations with 13-day period.** T.L.Duvall,Jr., H.P.Jones, J.W.Harvey (Kitt Peak Nat. Obs., Tucson, AZ, USA).
Nature (GB), vol.304, no.5926, p.517-18 (11 Aug. 1983).
Examines photoelectric drift-scan measurements of the solar diameter and full-disk magnetograms taken at Kitt Peak National Observatory for evidence of variations corresponding to the velocity oscillations of the 13.1-day period. An upper limit on radius variations is reported which is a factor of six below the amplitude needed to explain the velocity observations as a radial oscillation and the possible role of the rotation of large-scale surface magnetic features is considered. (8 refs.)

111014 **New measurements of the solar diameter.** J.H.Parkinson (Mullard Space Sci. Lab., Univ. Coll. London, Dorking, England).
Nature (GB), vol.304, no.5926, p.518-20 (11 Aug. 1983).
Measurements made during the 31 July 1981 total eclipse together with a reanalysis of previous eclipse and Mercury transit measurements confirm that there is no evidence for any secular change in the solar diameter, with a reduced upper limit. However, there is increased support for an ~80-yr cyclic variation. (14 refs.)

111015 **Internal rotation of the Sun.** H.C.Spruit (Max-Planck-Inst. fur Phys. und Astrophys., Garching, Germany), E.Knobloch, I.W.Roxburgh.
Nature (GB), vol.304, no.5926, p.520-2 (11 Aug. 1983).
The conditions for the occurrence of hydrodynamic instabilities in a radiative stellar interior are reviewed assuming that the rotation is constant on spheres. The instability with the lowest threshold is a double diffusive one, the axisymmetric baroclinic diffusive instability. A minimum rotation curve for the present Sun is calculated using the assumption that the efficiency of this instability is sufficiently high that the rotation of the Sun is close to marginal stability. This lower limit to the internal rotation rate is roughly consistent with present observations of the rotational splitting of solar oscillations. (19 refs.)

111016 **Solar radius change between 1925 and 1979.** S.Sofia (Lab. for Planetary Atmospheres, Goddard Space Flight Center, NASA, Greenbelt, MD, USA), D.W.Dunham, J.B.Dunham, A.D.Fiala.
Nature (GB), vol.304, no.5926, p.522-6 (11 Aug. 1983).
By analysing numerous reports, from different locations, on the duration of totality of the solar eclipses on 24 January 1925, and on 26 February 1979, it is found that the solar radius at the earlier date was 0.5 arc s, or 375 km larger than at the later date. The correction to the standard solar radius found for each eclipse was different when different subsets of the observations were used (for example, edge of path of totality timings compared with central timings), suggesting the existence of systematic inaccuracies in the lunar figure. However, the differences between the corrections for both eclipses were very similar for all subsets considered, indicating that changes of the solar size may be reliably inferred despite the existence of the lunar figure errors, as long as the proper consideration is made of the distribution of the observations. These results are considered strong evidence in support of the occurrence of solar radius changes on shorter than evolutionary time scales. (13 refs.)

111017 **Limits on the Sun's core magnetism from solar oscillations.** W.Dziembowski (N. Copernicus Astron. Centre, Polish Acad. of Sci., Warsaw, Poland), P.R.Goode.
Nature (GB), vol.305, no.5929, p.39-42 (1 Sept. 1983).
The authors perform an analysis of oscillation data due to Hill et al. (1982) to show that limits of a few megagauss can be placed on poloidal and toroidal magnetic fields inside the Sun. A limit can also be placed on the part of the quadrupole moment of the Sun due to magnetism. These fields are too weak to induce a quadrupole moment much larger than that which would result if the Sun rotated rigidly at the observed surface equatorial rate. (10 refs.)

111018 **Analysis of the polarization measurements during the occultations of the Crab Nebula by the plasma surrounding the Sun in 1977-1982.** N.S.Soboleva, G.M.Timofeeva.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.409-14 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Measurements of the Faraday rotation in the solar corona in the course of occultations of the Crab Nebula in 1977-1982 are reported. During this period the nebulae moved southward of the Sun and approached the Sun at a distance of about $5R_\odot$. It is found that during the whole 11-year solar cycle (1971-82) the negative rotation measure dominated (magnetic field being directed from the observer). This effect can be explained neither by radial, nor dipole, nor spiral solar magnetic field models. (8 refs.)

111019 **Solar activity.** D.M.Rust (American Sci. & Engng. Inc., Cambridge, MA, USA).
Rev. Geophys. & Space Phys. (USA), vol.21, no.2, p.349-60 (March 1983).
Reviews magnetic field emergence, active regions, flare buildup, eruptive prominences, coronal transients, impulsive phenomena and atmosphere flare effects. (186 refs.)

111020 **Sizes of turbulence elements in the solar atmosphere.** R.I.Kostyk (Main Astron. Obs., Acad. of Sci., Ukrainian SSR).
Sov. Astron. (USA), vol.26, no.6, p.703-5 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1167-70 (Nov.-Dec. 1982).
The average size of turbulent vortices (the correlation length) in the solar atmosphere decrease with height from 670 ($h=160$ km) to 440 km (h-250

km), while their root-mean-square velocity is constant and equal to 1.7 km.sec^{-1}. (22 refs.)

111021 On the statistical stability of solar cyclicity. K.S.Voichishin, M.I.Stodilka (Physicomech. Inst., Acad. of Sci., Ukrainian SSR).
Sov. Astron. (USA), vol.26, no.6, p.705-11 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1171-83 (Nov.-Dec. 1982).
A form function for the 11-year solar-activity cycles is introduced for an interval equal to the duration of the cycles, with allowance for the asymmetry of the latter. A mathematical model is proposed to describe the time structure of solar cyclicity. A method and algorithm for optimal estimation (in the sense of the minimum of the root-mean-square deviation) of its parameters are described. The statistical correlation of parameters of 11 year cycles is discussed and the stability of their fine structure is illustrated. The residual dispersion is calculated with allowance for all 20 cycles of the Zurich numbering (after subtracting from the initial data their approximated values). Attention is drawn to the uniformity of its variation from cycle to cycle as a test of the statistical stability of the shape of the latter. The sources of disruption of the indicated uniformity for monthly average observed Wolf numbers are calculated and ways of eliminating them are indicated. It is concluded that the statistical stability of the shape of the 11-year solar-activity cycles is real to within the variation of their asymmetry. (24 refs.)

97.00 STARS

97.10 STELLAR CHARACTERISTICS

111022 Long-period variables in the Magellanic Clouds: supergiants, AGB stars, supernova precursors, planetary nebula precursors, and enrichment of the interstellar medium. P.R.Wood, M.S.Bessell, M.W.Fox (Mount Stromlo & Siding Spring Obs., Res. School of Phys. Sci., Australian Nat. Univ., Canberra, Australia).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.99-115 (1 Sept. 1983).
Infrared *JHK* magnitudes and low-dispersion red spectra have been obtained for 90 long-period variables (LPVs) in the Small and Large Magellanic Clouds. The LPVs fall into two distinct groups, core helium (or carbon) burning supergiants and stars on the asymptotic giant branch (AGB). The AGB stars extend in luminosity right up to the AGB limit ($M_{\rm bol}\approx-7.1$). The existence of stars at the AGB limit provides direct evidence that the more massive AGB stars produce supernovae. Carbon star LPVs are confined to luminosities fainter than $M_{\rm bol}\sim-6$, in agreement with other studies of carbon stars in the Magellanic Clouds. Many of the oxygen-rich AGB stars show enhanced oxide bands of the *s*-process element Zr, indicating that dredge-up of material at helium shell flashes is occurring in these stars as well as in the carbon stars. The authors interpret the absence of carbon stars among the upper AGB stars. The authors deduce that stars with initial masses $\gtrsim 5\ M_\odot$ produce supernovae while less massive stars produce planetary nebulae with nebula masses from $\sim$0.1-2.1 $M_\odot$. (61 refs.)

111023 Stellar winds driven by multiline scattering. D.B.Friend, J.I.Castor (Joint Inst. for Lab. Astrophys., Univ. of Colorado, Boulder, CO, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.259-72 (1 Sept. 1983).
Presents a model of a radiation-driven stellar wind with overlapping spectral lines. It is based on the Castor, Abbott, and Klein (1975) (CAK) theory. The presence of overlapping lines allows a photon to be scattered many times in different lines. The authors assume a random separation between strong lines, which makes it possible to find the angular distribution of the wavelength-averaged intensity of radiation from the star. The properties of the wind at any point depend on this intensity, which in turn depends on the structure of the wind. A self-consistent wind model is found. (23 refs.)

111024 A new instability during nuclear shell burning. R.Kippenhahn, H.-C.Thomas (Max-Planck-Inst. fur Phys. & Astrophys., Inst fur Astrophys., Garching, Munchen, Germany).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.206-10 (Aug. 1983).
Shell burning can be vibrationally unstable. If a mass element in a region with nuclear burning is lifted the nuclear energy generation is reduced due to the decrease of the temperature in the element. It is therefore pushed back to its original position more violently than in the case without nuclear burning. This effect can sometimes overcome the damping and cause an overstability. With a linear stability analysis it is shown that the overstability in a helium burning shell of a 5 $M_\odot$ star can produce oscillations with a period of 0.1 s and a characteristic time of growth of 6 yr. (5 refs.)

111025 Stability of thermal relaxation oscillations. M.Barranco (Dept. de Optica, Univ. de Barcelona, Barcelona, Spain), J.R.Buchler, J.Perdang.
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.6-12 (Aug. 1983).
Demonstrates that a two-zone model for thermal relaxation oscillations (limit cycles), in, for example, thin He burning shells or in X-rays bursters, is vulnerable against an increase in the complication of the model structure, a property which is termed morphological instability. The inclusion of a third zone can completely destroy the limit cycle or else it can deform it. As a by-product of the analysis the authors find that a slight alteration of the structure of the model is inefficient in transforming the thermal pulses into 'chaotic' fluctuations. The result is indicative that the stochastic time behaviour, observed for the majority of X-ray bursters, if intrinsic, cannot be accounted for by a mere slight perturbational effect around the energy generating shell source. (14 refs.)

111026 The molecular weight barrier and angular momentum transport in radiative stellar interiors. E.Knobloch, H.C.Spruit (Max-Planck-Inst. fur Phys. und Astrophys., Inst. fur Astrophys., Garching, Munchen, Germany).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.59-68 (Aug. 1983).
The stability of a differentially rotating fluid with respect to axisymmetric instabilities is investigated in the presence of finite viscosity, thermal diffusion and a gradient of chemical composition, of diffusivity. The results confirm that the Goldreich-Schubert-Fricke instability is suppressed already at very small stabilizing composition gradients of the order $N_{\rm S}\approx\Omega$, where $N_{\rm S}$ is the buoyancy frequency due to the chemical gradient and Ω the rotation rate. This excludes the GSF instability as a mixing agent in chemically inhomogeneous stellar interiors. However, two other modes of instability exist, one of which is stabilized only by much stronger composition gradients of the order $N_{\rm S}\approx N_{\rm T}$ where $N_{\rm T}$ is the thermal buoyancy frequency. The other instability is triply diffusive in nature and is probably not very important since like the GSF instability it is limited to composition gradients with $N_{\rm S}\lesssim\Omega$. (31 refs.)

111027 Relaxation oscillations and double temperature structures in stellar coronae. A.G.Hearn, N.P.M.Kuin, P.C.H.Martens (Sterrenkundig Inst., Utrecht, Netherlands).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.69-74 (Aug. 1983).
Further work using the iterative method of Hearn and Vardavas (1981) for calculating stationary models for stellar coronae has shown that the coronae of small extent obtained with large fluxes of mechanical energy are not stable. It is suggested that the corona undergoes a relaxation oscillation in which a single extended corona collapses to a double corona which in turn builds up to a single extended corona again. An order of magnitude estimate of the period of the relaxation oscillation is more than 70d. Such a coronal relaxation oscillation may be an explanation for the observed variations of mass loss from late B and early A type supergiants and perhaps from Be stars. The inclusion of radiative forces resulting from the absorption of photospheric radiation by resonance lines is discussed. (32 refs.)

111028 Studies of the Carina Nebula. V. The near infrared excess of O-type stars and the anomalous extinction law in their environment. P.S.The, M.Groot (Astron. Inst., Univ. of Amsterdam, Amsterdam, Netherlands).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.75-82 (Aug. 1983).
For pt.IV see Astron. & Astrophys. Suppl. Ser. vol.41, no.1, p.93-107 (1980). From a photometric study of a sample of O, B and A-type stars located in the Carina Nebula, through 14 broad passbands between 0.3 to 4.0 μm, it is shown that the extinction law of the matter in the direction of the O-type stars is anomalous; this is not the case for most of the B and later type stars. The ratio of total to selective extinction of the O-type stars generally differs from star to star. (36 refs.)

111029 Transport properties of neutrinos in stellar collapse. I. Bulk viscosity of collapsing stellar cores. L.J.van den Horn (Astron. Inst., Univ. of Amsterdam, Amsterdam, Netherlands), C.G.van Weert.
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.93-100 (Aug. 1983).
Presents a detailed kinetic theory calculation of the bulk viscosity due to neutrinos in interaction with a material medium representative of a collapsing stellar core. The general theory of bulk viscous dissipation in a relativistic imperfect fluid is outlined. In stellar collapse the bulk viscosity arises primarily from neutrino absorption by neutrons and electron capture on protons. Assuming these reactions to be in local chemical equilibrium, the authors solve the linearized relativistic neutrino transport equation for the case of bulk viscous dissipation. Owing to the equilibrium constraint, the solution is determined by a single absorption parameter. (32 refs.)

111030 X-rays from stars. L.Golub (Harvard-Smithsonian Center of Astrophys., Cambridge, MA, USA).
Astronomy (USA), vol.11, no.9, p.66-70 (Sept. 1983).
Discusses solar X-ray emission and flares. The role of magnetic fields is discussed. Implications of these results for stellar emission are considered. Coronal emission is discussed. (no refs.)

111031 Radial velocities of bright southern stars. III. Late-type standard stars at 12 Å mm^{-1}. J.Andersen, B.Nordstrom (Copenhagen Univ. Obs., Copenhagen, Denmark).
Astron. & Astrophys. Suppl. Ser. (France), vol.53, no.2, p.287-90 (Aug. 1983).
For pt.II see ibid., vol.52, no.3, p.479-82 (1983). Radial velocities have been measured on 51 spectrograms of 14 late-type standard stars, taken with the ESO 1.5 m telescope and coude spectrograph at a dispersion of 12.4 Å mm^{-1} (IIa-O emulsion). A list of 15 suitable lines and wavelengths for radial velocity determination in late-type spectra is established. Using these lines, the internal and external standard errors for a single plate are discussed. (15 refs.)

111032 On the effect of temperature fluctuations on line intensities. P.Gouttebroze (Lab. de Phys. Stellaire et Planetaire, Verrieres-le-Buisson, France).
J. Quant. Spectrosc. & Radiat. Transfer (GB), vol.30, no.3, p.193-211 (Sept. 1983).
Investigates the effects of temperature fluctuations in a stellar atmosphere on the intensities of the lines emitted by a multilevel atom, by differentiating the coupled set of radiative transfer and statistical equilibrium equations. The authors propose a numerical method for the fast computation of large sequences of line profiles when the atmospheric temperatures are fluctuating about a mean curve $T(z)$ (oscillations, waves, turbulence, etc...). This method is applied to a three-level atom simulating the formation of Ca(II) lines in the solar atmosphere and the results are compared with those of direct computations. The authors show how the variations of atomic level populations, line source functions, and emergent intensities, may be related to temperature variations by a sum of several terms corresponding to each atomic transition and arising from the variations of collisional excitation rates. Finally, the

authors discuss the possibility of extending the method to compute profile variations when temperatures, densities and velocities are changing simultaneously within the atmosphere. (13 refs.)

111033 On the excitation of oscillations of stars at their encounters. A.G.Kosovichev, A.B.Severnyi.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.424-31 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
The oscillations arising at close encounters of stars is considered with the aid of numerical methods in linear adiabatic approximations. It is shown that two types of oscillatory motions appear due to the action of tidal force. It is suggested that the 160-min oscillation of the Sun can be a relict phenomenon of encounter of the Sun with a low-mass star, or a cloud. It is also pointed out that the oscillations arising at close encounters are very similar to those of β Cephei stars. (29 refs.)

111034 The wave turbulence spectra in a polytropic atmosphere. E.N.Pelinovskii, N.S.Petrukhin.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.445-8 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
In the weak turbulence approximation, the energy spectrum of acoustic-gravity waves in a polytropic atmosphere is shown to be of the form: $E(k) \propto k^{-9/4}$, $E(\omega) \propto \omega^{-7/2}$. (9 refs.)

111035 Outer atmospheres of late stars. M.M.Katsova (P.K. Shternberg State Astron. Inst., Moscow, USSR).
Sov. Astron. (USA), vol.26, no.6, p.678-83 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1124-33 (Nov.-Dec. 1982).
The short-wavelength spectra of the stars UX Ari during flare activity and in the quiet state and RW Aur are analyzed. An independent determination of the electron density made it possible to draw the reliable conclusion from the line intensities that the extent of the transition region between chromosphere and corona is considerably greater for these stars and Capella than for the Sun. Two groups of stars are distinguished: (1) rotating red dwarfs; (2) subgiants belonging to systems of the RS CVn-type and T Tau-type stars. The former are characterized by coronal loops emitting in the X-ray region. The appearance of considerble fluxes in lines of ions with $T_i \approx 10^5$K in stars of the latter group without X-ray enhancement is connected with direct heating with $T=10^4$-10^5K and with the development of upward-intensifying motions. Such a dynamical model of the outer atmosphere differs considerably from the usually considered outflow of the solar-wind type, efficiently cooling the coronas of stars with low gravity. (24 refs.)

97.20 NORMAL STARS (BY CLASS): GENERAL OR INDIVIDUAL

111036 Infrared observations of R136, the central object of the 30 Doradus Nebula. N.Panagia (Istituto di Radioastron., CNR, Bologna, Italy), E.G.Tanzi, M.Tarenghi.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.123-30 (1 Sept. 1983).
Photometric observations of R136 in the *J*, *H*, *K*, and *L* infrared filters, reveal the presence of strong excess radiation produced by stellar wind. From model fitting of the infrared continuum determine (*a*) the slope of the velocity variation with radius, (*b*) the mass loss rate, and (*c*) the stellar radius, which is determined in an implicit form as a function of the temperature. Adding information derived from the ionization of the 30 Doradus Nebula, the authors determine an ultraviolet brightness temperature and a total luminosity. This confirms that the stellar mass must exceed 2000 $M_\odot$. The comparable amounts of momentum carried by the wind and the radiation field indicate that the mass loss characteristics of R136 are closer to those of O-type stars rather than W-R stars. Combining the mass loss and luminosity values of R136 with those of galactic supergiants, the authors derive a *M-L* relationship. (36 refs.)

111037 X-rays and rotation among post-T Tauri G stars in Orion Ic. M.A.Smith (Sacramento Peak Obs., Sunspot, NM, USA), S.H.Pravdo, W.H.-M.Ku.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.163-6 (1 Sept. 1983).
V_R sin *i* values and X-ray luminosities are combined for a number of post-T Tauri G stars in the Orion Ic cluster. The results show that rapidly rotating, 1-2 $M_\odot$ G stars actually exhibit stronger X-ray emission than do T Tauri stars. There appears to be a general correlation between L_x/L_{bol} and V_R sin *i*; the indicated exponent of the relation, ~0.5, appears to be slightly smaller than that found for a similar relation for moderately rotating *G-K*, class II-V stars. The shallowness in slope with increasing rotational velocity could indicate that the average surface magnetic flux saturates with increasing magnetic activity and rotational velocity. The existence of circumstellar disks around the X-ray emitters implies that the site of X-ray emission is close to the stellar surface. There is evidence that these disks partially absorb the X-rays in some or all cases. The authors suggest that any coronas in these stars cannot extend more than ~one-half R^* near the equatorial plane. (24 refs.)

111038 A search for X-rays from runaway stars. C.K.Kumar, T.R.Kallman, R.J.Thomas (Howard Univ., Washington, DC, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.219-22 (1 Sept. 1983).
Enhanced X-ray emission from an early-type runaway star would be direct evidence for the presence of a collapsed companion, and thus for its origin as the result of a supernova explosion in a massive binary. To test this idea, measurements of X-ray fluxes in the 0.5-3 keV energy range from nine O and B type runaway stars were made with the Einstein Observatory. In each case, the X-ray luminosity observed does not exceed that expected from a normal OB star. Therefore the authors conclude that, if the runaway stars have collapsed companions, the separations of the components must be much greater than those in normal OB binaries. (15 refs.)

111039 Outer atmospheres of cool stars. XIII. Capella at critical phases. T.R.Ayres (Lab. for Atmospheric & Space Phys., Univ. of Colorado, Boulder, CO, USA), F.H.Schiffer, J.L.Linsky.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.223-33 (1 Sept. 1983).
For pt.XII see ibid., vol.260, no.2, p.670-94 (1982). Presents a high-dispersion ultraviolet study of the late-type spectroscopic binary Capella covering critical phases−three quadratures and one conjunction−in the orbit, as observed with the International Ultraviolet Explorer. The authors' work supports the conclusion reached by Ayres and Linsky (1980), that the rapidly rotating F9 III secondary star in the system is considerably brighter than the more slowly rotating G6 III primary in ultraviolet emission lines. The enhanced ultraviolet emission of the Capella giants compared to other yellow giants in recent *IUE* low-dispersion surveys suggests that the primary and secondary both are crossing the Hertzsprung gap for the first time. If the Capella giants indeed are both first crossers, then the spin-down of stars evolving through the Hertzsprung gap may be quite rapid. The authors conclude that the extraordinary brightness of the Capella secondary in the far-ultraviolet is a transitory, dynamic magnetic phase in the post-main-sequence evolution of moderately massive (~3 $M_\odot$) stars. (44 refs.)

111040 Some constraints on the color-magnitude diagram of giants in the galactic spheroid. J.N.Bahcall, R.M.Soneira (Inst. for Advanced Study, Princeton, NJ, USA), D.C.Morton, K.P.Tritton.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.627-34 (15 Sept. 1983).
The color-magnitude diagram of giants in the galactic spheroid is shown to be important in determining the number-color histogram of stars brighter than $B=19$ mag. This result is demonstrated by comparing a standard Galaxy model with observations of 391 stars in a field in the direction of Aquarius ($l=36.5°$, $b=-51.1°$). (39 refs.)

111041 The Al I-cyanogen correlation in the spectra of globular cluster red giants and the origin of intracluster heavy element variations. J.Norris, G.H.Smith (Mount Stromlo & Siding Spring Observatories, Woden, Australia).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.635-45 (15 Sept. 1983).
A spectroscopic survey of CN-strong/CN-weak pairs or groupings of stars in seven globular clusters has been made to ascertain if there is a positive correlation between the behavior of the resonance lines of Al I at 3944 and 3965 Å and that of the CN bands, as has been reported in NGC 6752. It is found that in five of the clusters such a correlation exists, but that in M4 and 47 Tucanae the Al I lines appear not to vary between the CN-strong and CN-weak groups. The implications of the results and the other abundance patterns of these systems for the origin of intracluster C, N, Na, Al, and heavy *s*-process element variations are considered. (51 refs.)

111042 G74−7: a true DA,F (DAZ) white dwarf. P.Lacombe (Dept. de Phys. & Observatoire du Mont Megantic, Univ. de Montreal, Montreal, Quebec, Canada), J.Liebert, F.Wesemael, G.Fontaine.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.660-4 (15 Sept. 1983).
Reports the first results of an observational attempt to confirm the existence of DA,F white dwarfs (cool, hydrogen-rich with calcium lines) using precision digital spectrophotometry. High-resolution observations of 16 cool white dwarfs ($T_e \lesssim 9500$K), variously classified as DA, DA,F, or DF stars have been carried out. This survey has yielded only one object, G74−7, with a sharp and narrow Ca II K-line of equivalent width 0.7 Å. The corresponding photospheric calcium abundance in G74-7 is Ca/H$\sim 1.2\times 10^{-9}$, and the line profile is consistent with theoretical predictions. The origin of the observed calcium is discussed and it is shown that the heavy element diffusion time scale in the envelope is short compared to the evolutionary time scale of the white dwarf suggesting a recent encounter with an interstellar cloud. (27 refs.)

111043 Outer atmospheres of cool stars. XIV. A model for the chromosphere and transition region of beta Ceti (G9.5 III). K.Eriksson (Joint Inst. for Lab. Astrophys., Univ. of Colorado, Boulder, CO, USA), J.L.Linsky, T.Simon.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.665-77 (15 Sept. 1983).
For pt.XIII see ibid., vol.272, no.1, pt.1, p.223-33 (1983). Computes a model for the chromosphere and transition region of β Ceti (G9.5 III) consistent with *IUE* spectra of the resonance lines of Mg II, C II and C IV. The authors treat the Mg II *h* and *k* lines in partial redistribution and the C II and C IV lines in complete redistribution. A good match to the observed line profile fluxes and to the Mg II *k* line profile is achieved for a hydrostatic equilibrium one-component model with temperature plateaus at 5500K and 22500K, but this model is not unique. Computed line fluxes are presented for a range of models to show the range of permitted temperature structures. (61 refs.)

111044 Late stages of stellar evolution. II. Mass loss and the transition of asymptotic giant branch stars into hot remnants. D.Schonberner (Louisiana State Univ. Obs., Baton Rouge, LA, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.708-14 (15 Sept. 1983).
Computes the transition of asymptotic branch giants of 0.8 and 1.0 $M_\odot$ into remnants of 0.565, 0.553, and 0.546 $M_\odot$ by means of mass loss which removes the stellar envelopes in about 10^3 yr. The remnants then evolve across the H-R diagram to the white dwarf configuration and their relevance for central stars of planetary nebulae is studied. From the temporal evolution of these models lower limits for mass and luminosity of central stars of ~0.55 $M_\odot$ and ~2500 $L_\odot$ are determined. (26 refs.)

111045 The atmosphere of Canopus. II. Chemical composition. Determination of the mass, radius, luminosity, and age. L.S.Lyubimkov, A.A.Boyarchuk (Crimean Astrophys. Obs., USSR).
Astrophysics (USA), vol.18, no.4, p.341-8 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.596-607 (Oct.-Dec. 1982).
For pt.I see Astrofizika, vol.18, no.3, p.375-85 (1982) or Astrophysics, vol.18, no.3, p.228-34 (1983). The model found earlier (Boyarchuk and Lyubimkov, 1982) is used to determine the abundances of 21 elements in the atmosphere of Canopus. The analysis is based on relatively weak lines in order to reduce the influence of inaccuracies in the microturbulence and in the damping. The chemical composition of the atmosphere of Canopus is found to be similar to the solar composition. By comparison with evolution calculations, the mass, radius, luminosity, and age are found for the supergiants α Car, α UMi, and

γ Cyg. It is shown that the extension of the atmospheres of these stars is small compared with their radii. (24 refs.)

111046 Stellar deuterium abundance: a new upper limit in Canopus. R.Ferlet (European Southern Obs., Garching, Munchen, Germany), M.Dennefeld, M.Spite.
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.172-4 (Aug. 1983).
Canopus is a supergiant star, with a mass near 10 $M_{\odot}$, which could have retained its original deuterium during contraction to the main sequence. From high resolution, high signal to noise ratio observations of Hα, a new upper limit for the D/H ratio of 5×10^{-7} by number has been obtained. This upper limit is below the lowest observed ratio in the interstellar medium showing the depletion effect on the initial deuterium abundance by stellar evolution. (17 refs.)

111047 Notes on the heavily reddened and variable A-type supergiant CD$-33°12119$. A.M.van Genderen (Leiden Obs., Leiden, Netherlands), G.Hammerschlag-Hensberge, P.S.The.
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.197-205 (Aug. 1983).
The results of photometric measurements (0.3 to 5 μm) and a spectroscopic study of the variable A2 Ia-type star CD$-33°12119$ are presented. The visual brightness variation of the star shows a peak-to-peak amplitude of $\sim$0.2 and a characteristic period of $\sim$35 d. The most striking phenomena of the visual spectrum are the extremely strong P Cygni profiles of Hα and Hβ. The extinction-free spectral energy distribution fits a theoretical Kurucz LTE model-atmosphere of $T_{\rm eff}=10000$K and log $g=1.5$. These physical parameters fit the *P-L-C* relation for variable supergiants reasonably well. (29 refs.)

111048 A search for rapid spectroscopic variability in the early type supergiants γ and θ Ara. D.Baade (European Southern Obs., Garching, Munchen, Germany).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.211-15 (Aug. 1983).
Twenty high-dispersion Reticon spectra of the Si III $\lambda\lambda$ 4552-74 triplet and Hα show variable line profiles of γ Ara (B1 Ib) and θ Ara (B2 Ib). The Si III lines of γ Ara are asymmetric, and changes even occur within one hour. There are indications of multiple absorption components. There are reasons to believe that this variability can be explained by pulsation. θ Ara, being 2500K cooler, did not show a similar behaviour. It was instead found in two different states lasting at least 8 and 6 nights, respectively. The change from one state to the other was not directly observed, but it took place within one day. (16 refs.)

111049 Spectroscopy and infrared photometry of southern T Tauri stars. I.Appenzeller, I.Jankovics (Landessternwarte Konigstuhl, Heidelberg, Germany), J.Krautter.
Astron. & Astrophys. Suppl. Ser. (France), vol.53, no.2, p.291-309 (Aug. 1983).
Obtains flux calibrated low resolution ($\Delta\lambda\approx7$ Å FWHM, $4200<\lambda<6800$ Å) IDS spectrograms, medium resolution image tube spectrograms ($\Delta\lambda=1.4$ Å, $3650<\lambda<4600$ Å or $\Delta\lambda=1.8$ Å, $3800<\lambda<5000$ Å) and infrared photometry of southern T Tauri stars. The results are presented in a format similar to that of the corresponding northern hemisphere data of Cohen and Kuhi (1979). (25 refs.)

111050 An investigation of short timescale variability in 6 early B stars. C.Stagg (Dept. of Astron., Univ. of Toronto, Toronto, Canada).
Inf. Bull. Variable Stars (Hungary), no.2376, p.1-6 (1 Aug. 1983).
Reports photometric observations during September 1982 of six early B-type stars which have been suspected of short period variability. Light variations were observed in V358 Persei, 2 Vulpeculae and V819 Cygni; however, these variations could not be fitted to previously reported periods. No variations were observed in 1 Camelopardalis (HR 1417), HR 8105 or V568 Cygni. In addition two of the check stars, HD 13970 (B5 Ib) and HR 7577 (F2 V) showed light variations on a time-scale of hours. (12 refs.)

111051 UBV observations and a photometric sequence for the highly active T Tauri star VY Tau. R.P.S.Stone (Lick Obs., Mt. Hamilton, CA, USA).
Inf. Bull. Variable Stars (Hungary), no.2380, p.1-4 (8 Aug. 1983).
The author presents photoelectric UBV photometry and a finding chart for a sequence of 15 stars in the field of the violently variable T Tauri star VY Tauri. In addition six photoelectric observations of VY Tauri itself, covering the period September 1972 to November 1981, are reported. It is found that these measurements were obtained within a period of relative inactivity of the variable star. (4 refs.)

111052 Abundance sensitive parameters for red giants in globular clusters. T.L.Evans (South African Astron. Obs., Cape Town, S Africa).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.945-59 (Sept. 1983).
Photoeletric VI_{KC} photometry yields structural parameters for the giant branch in nine clusters. Three features are studied spectroscopically in the 5000-6200 Å region. The TiO bands are closely correlated with V-I colour and do not provide an independent abundance criterion. The Mg b lines depend on abundance but lose sensitivity at high metal content, apparently because of the strengthening of the overlapping MgH bands. The NaD lines are adversely affected by interstellar absorption and atmospheric emission. They show a wide scatter at a given colour in 47 Tuc, similar to that found among hotter stars, as well as a strong positive correlation with metal abundance. These and other parameters obtained from photometry and low-resolution spectroscopy order the clusters in a similar way which is at variance with the results of abundance analyses based on high-dispersion spectroscopy. (69 refs.)

111053 A color-selected magnetic white dwarf. R.A.Downes (Dept. of Astron., Univ. of California, Los Angeles, CA, USA), B.Margon.
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.358-60 (June 1983).
During a survey for ultraviolet-excess objects in the plane of the Galaxy, the authors have discovered at 15th-magnitude white dwarf with an unusual absorption spectrum. The features are shown to be resolved Zeeman components of hydrogen in a magnetic field of $\sim13\times10^{6}$ gauss. Thus, this is one of the rare magnetic white dwarfs found via color selection. (10 refs.)

111054 Null results from a survey for pulsating DB white dwarfs. E.L.Robinson, D.E.Winget (Dept. of Astron., Univ. of Texas, Austin, TX, USA).
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.386-7 (June 1983).
The authors describe the survey in which the pulsating DB white dwarf GD 358 was found, and present a list of the DB white dwarfs observed in the survey that did not have detectable pulsations. It is shown that there are probably no pulsational instability strips for the DB white dwarfs at temperatures less than 20000K. (10 refs.)

111055 On the origin of coronae, stellar winds and microturbulence in early-type stars. A.Z.Dolginov, V.A.Urpin.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.360-3 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
The meridional circulation in early-type stars is considered. It is shown that turbulent velocities generated by meridional flows are of the order of 1-10 km/s in A-B-O stars and are in good agreement with the observed velocities of microturbulence. Acoustic waves generated by turbulence are the sources of energy to heat the coronae. Coronae of O and B stars can emit 10^{34} erg/s in UV and X-rays and can be hot enough to be the sources of strong stellar winds. (12 refs.)

111056 Polarization of stars in R-associations: observational data. N.V.Voshchinnikov, P.E.Marchenko (Leningrad Univ., Leningrad, USSR).
Sov. Astron. (USA), vol.26, no.6, p.673-7 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1115-23 (Nov.-Dec. 1982).
Polarimetric data are assembled for 95 stars that are illuminating reflection nebulae. Most of these belong to 18 standard R-associations. The observed dependence of the percentage polarization P on wavelength and color excess E_{B-V} suggest that the unpolarized light of R-association members may become polarized as it traverses an ensemble of dust grains aligned by a magnetic field which in some cases (Tau R2, Ori R1/R2, Sco R1, Cep R2) is intrinsic to the association. In certain R-associations the grain size is variable and the stochastic magnetic field component fluctuates on a scale of 10-30 pc. (33 refs.)

97.30 VARIABLE AND PECULIAR STARS

(inc. novae)

111057 Hα observations of four novae in M31. R.Ciardullo, H.Ford (Univ. of California, Los Angeles, CA, USA), G.Jacoby.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.92-8 (1 Sept. 1983).
On-line off-line Hα plates of M31's nucleus revealed four bright stellar objects ($m_R\approx14.9$, 15.0, 15.8, 16.4) within 1.2 kpc of the galaxy center. Spectrophotometric observations made 10 days later showed the stars were novae in the stage of early decline. In the 10 day interval, the Hα emission from these novae faded less than a magnitude, despite the fact that their continua had long since faded from view. The high luminosity and long decay time of the Hα emission suggest it might take an excellent standard candle for extragalactic distance measurements. (27 refs.)

111058 A comment on red supergiant variables in the SMC. J.A.Frogel (Cerro Tololo Inter-American Obs., Casilla, La Serena, Chile).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.116-17 (1 Sept. 1983).
Infrared photometric observations of two suspected supergiant carbon stars in the Small Magellanic Cloud (SMC) show that these stars have mean luminosities no greater than those of known C stars in the Clouds and hence are not candidates for the 'missing' bright C stars. Some suspected supergiant counterparts to oxygen rich Mira-type variables are also shown to be quite distinct from supergiants and are more likely luminous asymptotic giant branch stars. (13 refs.)

111059 The evolutionary state and pulsation characteristics of red variables in globular clusters. J.A.Frogel (Cerro Tololo Inter-American Obs., Casilla, La Serena, Chile).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.167-74 (1 Sept. 1983).
Infrared photometry, effective temperatures, and bolometric magnitudes for more than 50 red giant variables in globular clusters are assembled and discussed. All of the long-period variables (LPVs) in the clusters have luminosities greater than that corresponding to core helium flash, so they must be asymptotic giant branch (AGB) stars. Why luminous AGB stars (the LPVs) are only in metal-rich clusters is not understood. Part of the explanation probably lies in higher red giant masses in clusters of higher metallicity. Red *K-L* colors for the LPVs are probably indicative of relatively high mass loss rates compared to the non-LPV variables. Those red variables which lie at considerably warmer temperatures than the giant branches of their clusters could be AGB stars, and some may have circumstellar shells. (46 refs.)

111060 The circumstellar dust of mu Cephei. C.Rogers, P.G.Martin, D.R.Crabtree (Scarborough Coll., Univ. of Toronto, Toronto, Ontario, Canada).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.175-81 (1 Sept. 1983).
An accurate solution to the equation of transfer in spherical geometry (including an anisotropic phase function) is used to model *IUE* observations of the circumstellar extinction of μ Cep. Some grain materials can thus be eliminated from consideration while others can be restricted in grain size (and envelope optical depth). Further discrimination of candidate grain models is achieved through analysis of the thermal infrared emission. It is found that circumstellar dust similar to basaltic glass with enhanced near-infrared absorptivity would satisfy observations in both wavelength regimes. (17 refs.)

111061 Confirmation among visual multiples of an increase of Ap stars with age. H.A.Abt (Kitt Peak Nat. Obs., Tucson, AZ, USA), O.Cardona.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.182-9 (1 Sept. 1983).
Open clusters with ages below certain threshold values contain no Ap stars and those with greater ages contain numbers of Ap stars that apparently increase with age. But in view of the few young clusters studied, the data could also be interpreted in terms of random differences in the frequencies of Ap stars between individual clusters, rather than an age effect. The authors therefore obtained data on 77 field visual multiple systems (that originated from many different clusters and associations) in which the primaries are O5-A1 stars and the secondaries occur in the absolute magnitude range of the Ap stars. Again spectral classification shows no Ap stars in systems with ages $\leq 10^6$ yr and a steady increase in Ap stars thereafter. The numerical agreement with the cluster data is good, confirming that the cluster data are exhibiting a real age effect. (21 refs.)

111062 The massive WC6+O6-8 spectroscopic binary HD 94305. V.S.Niemela, R.H.Mendez (Inst. de Astron. y Fisica del Espacio, Buenos Aires, Argentina), A.F.J.Moffat.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.190-5 (1 Sept. 1983).
HD 94305 is found to be a double-lined WC6+O6-8 spectroscopic binary. The minimum masses of the components of this binary are 15 $M_\odot$ and 32 $M_\odot$ for the Wolf-Rayet and the O type components, respectively. The relatively high minimum mass for the WC6 component adds further evidence to the notion presented by Niemela (1981) that the more massive WC6-8 stars cannot be descendants of the less massive WN3-5 stars. (16 refs.)

111063 HD 164615: a probable spotted single F type star. H.A.Abt (Kitt Peak Nat. Obs., Tucson, AZ, USA), G.Bollinger, E.W.Burke,Jr..
Astrophys. J. (USA), vol.272, no.1, pt.1, p.196-201 (1 Sept. 1983).
This star shows light variations by 0.05 mag in a period of about 0.815^d, but there are substantial differences from cycle to cycle. The authors explore various possible explanations for the variations. First, the star is not an Ap variable because its spectrum is normal (F2 IV) and it does not have the color variations that are typical of an Ap star. It is not an ellipsoidal primary because the radial velocity does not change; a lack of change in line widths excludes the possibility of its being a double-lined binary with unresolved lines. It is probably not a pulsating star because of the lack of color and velocity changes. However, the hypothesis of a single rotating spotted star fits because the rotational period (1.7^d sin *i*) is compatible with the light period (0.815^d) and it offers a natural explanation for changes from cycle to cycle in terms of changes in spot activity. (22 refs.)

111064 A search for light-time effects in binary Cepheids: AW Persei. N.R.Evans (Erindale Coll., Univ. of Toronto, Toronto, Ontario, Canada).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.214-18 (1 Sept. 1983).
Phase residuals in *O-C* diagrams for the classical Cepheid AW Persei are examined to see whether they produce periodic variations associated with binary orbital motion (the light-time effect). Variations of several standard deviations in the *O-C* diagram are consistent with a light-time interpretation. The available radial velocity information is in agreement with the size and timing of the light curve shifts. An orbital period of 20 years is derived from recent radial velocities. Mass estimates from the orbit are discussed. (23 refs.)

111065 On the nature of dwarf novae. J.Smak (Joint Inst. for Lab. Astrophys., NBS, Washington, DC, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.234-7 (1 Sept. 1983).
Observational data on mass transfer rates and radii of disks indicate that the outer parts of disks in novae and nova-like binaries are sufficiently hot for stationary accretion; those in dwarf novae are too cool to avoid an accretion instability; while those in Z Cam systems are the borderline cases. The mass ratios of novae and nova-like binaries with main-sequence secondaries appear—at a given orbital period—to be systematically larger than those of dwarf novae, implying that higher mass ratios are responsible for higher mass transfer rates. (28 refs.)

111066 Photoionization models for the winds from cataclysmic variables. T.R.Kallman (Center for Space Res., MIT, Cambridge, MA, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.238-44 (1 Sept. 1983).
Photoionization models are presented for the relative abundances of Si IV, C IV, and N V as a function of the ionization parameter and shape of the ionizing continuum spectrum in the EUV and X-ray energy range. These models are applied to the interpretation of the UV resonance lines observed from the cataclysmic variable TW Virginis by Cordova and Mason (1982). The observed lines are assumed to be formed in gas flowing supersonically out from the continuum source in the form of a stellar wind. It is shown that the shape of the ionizing spectrum can be determined without assuming that the outflow is spherical by fitting to ratios of the line strengths. Under the added assumption of spherical outflow the derived ionization parameter for the X-ray component can be used to constrain the total mass flux in the wind. (23 refs.)

111067 Element identifications in the ultraviolet spectrum of HD 101065. G.Wegner (Dept. of Phys. & Astron., Dartmouth Coll., Hanover, NH, USA), D.J.Cummins, P.B.Byrne, D.J.Stickland.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.646-59 (15 Sept. 1983).
Ultraviolet spectroscopic observations with the IUE satellite of the controversial peculiar star HD 101065 are presented and discussed. Low-resolution spectra combined with published visual and infrared broad-band photometry show that the star's spectral energy distribution is greatly distorted, presumably by the severe line blanketing. However, the presence of observable ultraviolet flux below 1900 Å suggests that HD 101065 is considerably hotter than 6000K. A detailed examination of the high-resolution spectrum of HD 101065 in the region 1900-3200 Å found that the lines of the iron-peak elements Fe II, Cr II, Mn II, and Ti II are strongly represented in the ultraviolet spectrum. The implications of the presence of these elements for the temperature estimate and nature of HD 101065 are discussed. (35 refs.)

111068 Spectrographic observations of the suspected delta Scuti variable beta Ari. A.Barbiano Di Belgioso, M.Fracassini, L.E.Pasinetti, P.Stroppa (Dipartimento de Fisica, Univ. de Milano, Milano, Italy).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.97-113 (July 1983).
Three sets of spectra (in all 85 spectra) of the well-known standard and high eccentricity spectroscopic binary star beta Ari were taken. These sets were taken during the periastron passage of 14-15 November 1976, after the periastron passage of 2-3 October 1977 and before the apastron passage of 23 November 1977. The analysis of the radial velocities RV and equivalent widths W_λ of hydrogen and metal lines show periodic variations similar to those of some classical delta scuti stars. The variations of the asymmetries of the profiles of H and Ca II K lines, linked to the variations of the RV seem to recall the Schuster effect observed in classical Cepheids. A periastron effect appears. A faint 'bump' in RV and W_λ curves of Ca II K line is singled out. (35 refs.)

111069 The magnetic field variation of the Ap star HR 465. G.Scholz (Zentralinst. fur Astrophys., Astrophys. Obs., Potsdam, Germany).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.159-63 (July 1983).
The magnetic field of HR 465 varies with a period of 23.3 yr. The number and intensity of the absorption lines show their extrema at the times of the cross-over points of the magnetic field in contrast to the phase relation of these quantities known for most short-time magnetic Ap stars. Apart from the variations produced by the binary motion no further general velocity changes were found. The radial velocity determined by lines of the neutral elements differ somewhat significantly from those of the ionized elements. The interpretation causes difficulties in all discussed models; a precession model seems to be a little more favourable than a rigid-rotator or alternating dynamo model. (9 refs.)

111070 Period-luminosities relation of classical Cepheids. G.R.Ivanov, N.S.Nikolov (Dept. of Astron., Univ. of Sofia, Sofia, Bulgaria).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.191-200 (July 1983).
A PL-relation for the Cepheids in the Galaxy, the Magellanic Clouds and M31 is constructed. On deriving this relation both the period-radius and period-colour relations are used. The distance moduli of the three galaxies under discussion are obtained. The colour-coefficient of period-colour-luminosity-relation is briefly discussed. (54 refs.)

111071 AB Aurigae and its variable hydrogen lines. U.Finkenzeller (Landessternwarte, Konigstuhl, Heidelberg, Germany).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.157-62 (Aug. 1983).
Coude spectrograms of dispersion 8 and 16 Å/mm of the variable Herbig Ae/Be star AB Aur are discussed. From this material and a 5.3 Å/mm echelle spectrogram of H_α and NaD a stellar wind, possibly decelerated, and a relatively compact emitting region close to the star are suggested. The latter region is variable on time scales of less than a day. The heliocentric radial velocity of AB Aur of $+21 \pm 10$ km s^{-1} is in agreement with $+15.3 \pm 0.6$ km s^{-1} observed for the associated molecular cloud. The possibility that AB Aur is a member in a close binary system is not supported. (5 refs.)

111072 The intrinsic properties of 29 Cepheids in the Magellanic Clouds. A.M.van Genderen (Leiden Obs., Leiden, Netherlands).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.223-35 (Aug. 1983).
The intrinsic properties of 29 long-period Cepheids in the Magellanic Clouds are derived applying individual reddening corrections. The temperature/colour relation is calibrated using the temperatures of the theoretical $V-B/B-U$ diagram. In order to match observations with the theoretical ML relations of Becker et al. (1977), distance moduli of 19.12 and 18.65 for the SMC and LMC, respectively, had to be adopted. The theoretical indication that at constant period Cepheids in their first crossing through the instability strip are brighter than in the other crossings, seems to be confirmed by the observations. PLT$_{eff}$ relations are determined. (37 refs.)

111073 Spectroscopic observations of the cataclysmic variable HL CMa during outburst. W.Wargau, A.Bruch, H.Drechsel, J.Rahe (Astron. Inst., Univ. Erlangen-Nurnberg, Bamberg, Germany).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.L1-4 (Aug. 1983).
Presents optical spectrophotometric observations of the cataclysmic system HL CMa during rise, maximum, and decline phase of an outburst. The spectral evolution is discussed. At maximum light, broad absorption troughs of the Balmer lines are visible. In addition, strong H, He I, He II, and CIII-NIII (4650 Å) emission is present. Radial velocity measurements reveal an orbital period of $0.2145^d \pm 0.0006^d$. The overall spectral behavior makes HL CMa an unusual cataclysmic variable. (6 refs.)

111074 Infrared colors of the chemically peculiar stars of the upper main sequence. W.K.Bonsack, H.M.Dyck (Inst. for Astron., Univ. of Hawaii, Honolulu, HI, USA).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.29-33 (Aug. 1983).
A program of *J, H, K, L′, M* photometry of CP stars and normal comparison stars has been carried out at the Mauna Kea Observatory. The infrared colors of the CP and normal stars are found to be similar to each other, and to the predictions of normal model atmospheres, to within at worst 20%. These results do not support the conclusion of Groote et al. (1980, 1981) that infrared excesses at 5 μm are found in CP stars wtih magnetic fields. (16 refs.)

111075 Non-LTE analysis of massive O stars. III. The O3 stars HD93128, HD93129 A, and HDE303308. K.P.Simon (Inst. fur Astron. und Astrophys., Univ. Munchen, Munchen, Germany), G.Jonas, R.P.Kudritzki, J.Rahe.
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.34-44 (Aug. 1983).
For pt.II see ibid., vol.118, no.2, p.245-54 (1983). The three stars HD 93128: O3V ((f)), HD 93129 A are analyzed by means of high-resolution, low-noise

coude spectra. The measurements of the equivalent width of He I λ4471 and of the Balmer and He II line profiles yield the helium abundance and effective temperatures and gravities. From the position in the log *g*-log T_{eff} diagram and from theoretical evolutionary tracks the authors deduce some results. From the distance of the ocean clusters Tr 14 and Tr 16 the authors evaluate radii and luminosities. (53 refs.)

111076 The old-nova GK Per (1901). III. Accretion disc models. A.Bianchini, F.Sabadin (Asiago Astrophys. Obs., Asiago, Italy).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.112-16 (Aug. 1983).
For pt.II see ibid., vol.106, no.1, p.176-8 (1982). The UV spectrum of the old-nova GK Per (1901) at quiescence greatly differs from those of the other observed old-novae. In spite of the presence of high excitation emission lines the UV to visual continuum energy distribution is peaked at ~3600 Å, whereas for most old-novae it steeply rises towards shorter wavelengths. The authors construct a grid of models of accretion discs around a magnetic white dwarf for two physically different cases. A modification of the standard disc model in which the inner edge of the disc does not reach the star fails to reproduce the observed X-ray to infrared energy distribution. A better fit is achieved with a disc model whose radial temperature distribution has been changed by the presence of magnetic field lines. (37 refs.)

111077 Stimulated emission and the flat Balmer decrements of cataclysmic variable stars. M.Elitzur, G.J.Ferland (Dept. of Phys. & Astron., Univ. of Kentucky, Lexington, KY, USA), W.G.Mathews, G.A.Shields.
Astrophys. J. Lett. Ed. (USA), vol.272, no.2, pt.1, p.L55-9 (15 Sept. 1983).
Balmer emission lines from cataclysmic variables often have nearly equal intensities rather than the rapid decrement predicted by simple nebular theory. Traditionally, this has been interpreted in terms of local thermodynamic equilibrium emission from a dense gas with small volume located just above the accretion disk. The authors show that the intense radiation field within a close binary system can affect excited-state populations and optical emission in ways which allow a relatively low density gas to closely mimic the high-density situation. In at least one case, the old nova V603 Aql, the emitting gas has a low density and nearly fills the orbital plane of the system. If this is characteristic of other systems, then the determination of orbital parameters and masses of cataclysmic variables from emission-line radial velocities, as well as the prediction of soft X-ray emission from accreting binaries, will be affected. (17 refs.)

111078 The orbital periods for six cataclysmic binaries. A.W.Shafter (Dept. of Astron., Univ. of California, Los Angeles, CA, USA).
Inf. Bull. Variable Stars (Hungary), no.2377, p.1-2 (1 Aug. 1983).
The orbital periods of VW Vulpeculae, V380 Ophiuchi, CM Delphini, TW Virginis, V794 Aquilae and SY Cancri have been determined from the radial velocity variations of their Hα emission lines. (5 refs.)

111079 The spectrum of VY Aquarii at minimum. E.M.Hendry (Corralitos Obs., Las Cruces, NM, USA).
Inf. Bull. Variable Stars (Hungary), no.2381, p.1-3 (10 Aug. 1983).
The author reports spectroscopic observations of the recurrent nova VY Aquarii on 17 and 18 July 1983. The star was at minimum at this time, with m≤16. The spectrum is that of a Be star with all the hydrogen lines visible in emission from Hβ to H11. He I emission lines and Ca IIK emission were also present. All the lines took the form of double emission-central absorption profiles, in which the violet emission was always the wider feature. Radial velocities are presented for all measurable features. There is considerable scatter in the velocities of the central absorptions, both on a single spectrum and from night to night; however, there is no consistent Balmer progression. (4 refs.)

111080 R CrB. G.M.Hurst.
Br. Astron. Assoc. Circ. (GB), no.637, 1 pp. (12 Sept. 1983).
It is reported that R Coronae Borealis has started to fade. A visual magnitude estimate of 6.8 is reported for 1983 August 26. (no refs.)

111081 GK Persei. G.M.Hurst.
Br. Astron. Assoc. Circ. (GB), no.637, 1 pp. (12 Sept. 1983).
A visual magnitude estimate of 10.6 is reported for 1983 August 15. It appears that GK Persei has reached a similar magnitude to that observed during the last mini-outburst in 1981. (no refs.)

111082 AG Draconis. R.Viotti, C.Eiroa, A.Cassatella, A.Altamore.
I.A.U. Circ. (USA), no.3855, 1 pp. (29 Aug. 1983).
It is reported that the Population II symbiotic star AG Draconis has now reached a minimum state following the active phase which began in 1980. Coordinated ultraviolet and infrared observations during June 1983 indicate that the ultraviolet continuum and line fluxes have decreased and are now close to the pre-outburst values. The equivalent width of He II 164 nm is much larger than at maximum, suggesting a higher temperature for the hot source. Small, probably irregular, light variations in JHKL were observed during 1981-1983, but these are not correlated with the UV variations. These observations confirm that the hot radiation source undergoes large-amplitude variations, whereas the cool star is more stable. (1 ref.)

111083 Novalike object in Libra. J.Maza.
I.A.U. Circ. (USA), no.3856, 1 pp. (29 Aug. 1983).
It is reported that this novalike object is present at m_{pg}=18.5 on the ESO B Survey and on essentially monthly exposures since 1980. A further observation on 1983 August 18 showed the object at m_{pg}~10. (1 ref.)

111084 GK Persei. M.Verdenet, I.Dalmeri, J.Bortle, E.Mayer, M.Cavagna, C.E.Spratt, C.Scovil.
I.A.U. Circ. (USA), no.3856, 1 pp. (29 Aug. 1983).
Visual and photographic magnitude estimates are reported for the period 1983 August 6 to 24. (no refs.)

111085 SU Tauri. J.Mattei.
I.A.U. Circ. (USA), no.3856, 1 pp. (29 Aug. 1983).
Reports visual magnitude estimates of this R Coronae Borealis variable for the period 1983 April 10 to August 21; the star is recovering from the minimum of October 1982. (2 refs.)

111086 KR Aurigae. J.Bortle.
I.A.U. Circ. (USA), no.3857, 1 pp. (29 Aug. 1983).
Reports visual magnitude estimates for the period 1983 August 10 to 16. (1 ref.)

111087 R Coronae Borealis. J.Mattei.
I.A.U. Circ. (USA), no.3857, 1 pp. (29 Aug. 1983).
It is reported that R Coronae Borealis has started to fade. Visual magnitude estimates are presented for the period 1983 August 10 to 25. (2 refs.)

111088 U Aquarii. J.Bortle.
I.A.U. Circ. (USA), no.3857, 1 pp. (29 Aug. 1983).
Reports visual magnitude estimates of this R Coronae Borealis star for the period 1983 July 21 to August 16. (no refs.)

111089 Observations of red variable stars in globular clusters. T.L.Evans (South African Astron. Obs., Cape Town, S Africa).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.961-73 (Sept. 1983).
Extensive observations of line strengths in the spectra of variable and constant stars in globular clusters show that while variable stars often have H emission lines, the H lines in variables of small amplitude often show stronger absorption than typical non-variable stars. Strong H emission is found in stars of smaller amplitude as well as in Mira variables, especially in the more metal-deficient clusters, and is often accompanied by a weakening of strong lines of neutral metals which is well known in Mira variables. The subdivision of red variables into Mira, semi-regular and supragiant branch stars, as well as small amplitude variables on the giant branch, is apparent in 47 Tuc: the extension of this subdivision to very metal-poor clusters, where generally small amplitudes and a prevalence of strong H emission complicate the situation, is discussed. (65 refs.)

111090 M and S stars in the Magellanic Clouds. T.L.Evans (South African Astron. Obs., Cape Town, S Africa).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.985-96 (Sept. 1983).
Digital spectra of 46 red stars in the field of the SMC and in globular clusters in both Magellanic Clouds reveal that 8 are K stars, 18 are M stars, 19 are early S stars and 1 is a foreground dwarf. Stars with B-V ~2 in the field of the SMC may be of type K, M or S, though a common explanation for the abnormal colours in terms of an enhanced C/O ratio seems likely. Most of the non-carbon stars brighter than $M_{bol}=-4.3$ in the clusters are S stars, which evidently represent an intermediate stage in the modification of atmospheric composition. Systematic trends with cluster age are tentatively outlined, indicating that the M→S and S→C transitions occur at higher luminosity and lower surface temperature in the younger (more massive) stars. (38 refs.)

111091 Symbiotic stars: spectrophotometry at 3-4 and 8-13 μm. P.F.Roche (Dept. of Phys. & Astron., Univ. Coll. London, London, England), D.A.Allen, D.K.Aitken.
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.1009-15 (Sept. 1983).
Presents infrared spectrophotometry of 20 symbiotic stars, mostly of the dust-rich variety. HDE 330036 is unique in showing an emission feature at 11.3 μm. The remainder combine a hot grey component and/or optically thin silicate emission. A model in which the grey component is due to optically thick silicate dust is not consistent with the spectra. The authors propose instead that iron-based grains, expected to form in the ejecta of cool stars, are heated by the ultraviolet radiation field of the hot companion. (19 refs.)

111092 Outburst period-energy relations in cataclysmic novae. G.T.Bath (Dept. of Astrophys., Univ. of Oxford, Oxford, England), J.van Paradijs.
Nature (GB), vol.305, no.5929, p.33-6 (1 Sept. 1983).
Shows that the behaviour of SS Cygni is in close agreement with theoretical predictions of dynamically unstable states of the red star when it fills the Roche-lobe, and is in conflict with the assumptions of early disk instability models. (18 refs.)

111093 γ-ray line emission from SS 433. R.C.Lamb, J.C.Ling, W.A.Mahoney, G.R.Riegler, W.A.Wheaton, A.S.Jacobson (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).
Nature (GB), vol.305, no.5929, p.37-9 (1 Sept. 1983).
Reports preliminary evidence for γ-ray line emission from the region of SS 433. The observations were accomplished with the high-resolution γ-ray spectrometer aboard the HEAO 3 satellite. One of the line features reported, located at an energy of 1.5 MeV, has a statistical significance of ~6 σ during a particular 18-day interval. Another feature appears near 1.2 MeV. The observed energies may be explained in terms of a kinematic model as blue- and red-shifted components of the 1.369-MeV line from a nuclear transition of ^{24}Mg from its first excited state to its ground state. (12 refs.)

111094 Spectrophotometry of Nova Muscae 1983. B.S.Shylaja (Indian Inst. of Astrophys., Bangalore, India).
Observatory (GB), vol.103, no.1055, p.203-4 (Aug. 1983).
Reports a spectral scan on 1983 February 4 when the nova appeared to be $\sim 11^m$. The observations were confined to the region from *Hβ* to *Hα*. Line identifications and comparisons with other nova spectra suggest that the nova was in the 'Orion' phase at the time. (6 refs.)

111095 Sk−71°34: a new Wolf-Rayet star in the Large Magellanic Cloud. P.S.Conti, C.D.Garmany (Dept. of Astrophys., Univ. of Colorado, Boulder, CO, USA).
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.411-12 (July 1983).
Reports the serendipitous discovery of a relatively weak-lined Wolf-Rayet star of the nitrogen sequence in the Large Magellanic Cloud. (13 refs.)

111096 HR 4912: a variable of the old-disk population. R.E.Luck (Dept. of Phys. & Astron., Louisiana State Univ., Baton Rouge, LA, USA), D.L.Lambert, H.E.Bond.
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.413-21 (July 1983).
HR 4912 is a luminous F-type star lying at a galactic latitude of +36°; it is also a low-amplitude variable with a 44-to 68-day period. It is shown that HR 4912 has a moderately low iron content: [Fe/H]=−1.2, implying that it derives from the old-disk population. The N/C ratio is large, indicating mixing of CNO-cycled material to the surface. The derived gravity implies an absolute magnitude $M_v \sim -4$. HR 4912 is probably evolving to the left off the asymptotic giant branch in the H-R diagram; it is suggested that it is an SRd-type variable. (47 refs.)

111097 The behavior of Hα in the 16-day Cepheid X Cygni. G.Wallerstein (Astron. Dept., Univ. of Washington, Seattle, WA, USA).
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.422-6 (July 1983).
Presents radial velocities of X Cyg from 19 spectra of 10 Å mm^{-1} obtained at the Dominion Astrophysical Observatory. All the spectra were taken between phases 0.6 and 0.2 so as to cover rising light very thoroughly. As with other long-period cepheids a redward displaced component of Hα appears near phase 0.80 and gradually descends to the center-of-mass velocity of the star where it remains from near phase 0.3 to the next maximum. A violet-shifted component appears near maximum and may be related to Ca II emission seen before maximum. The velocity curves of Hα are discussed in terms of velocity gradients in the outer envelope of X Cyg combined with the excitation of the metastable 2s state of hydrogen by trapped *Lα* and collisions. (15 refs.)

111098 New observations of six RV Tauri and SRd variable stars. D.L.Dupuy, J.W.B.Allwright (Dept. of Astron., Saint Mary's Univ., Halifax, Canada), D.W.Dawson, J.L.Africano.
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.427-32 (July 1983).
Differential photoelectric observations in the *b* and *y* filters of the four-color system have been obtained of five known or questionable RV Tau variable stars and one SRd variable, using the 1.2-meter telescope at Cloudcroft Observatory. These observations spanned roughly 180 days for TT Oph and V564 Oph, with 40 to 50 observations each (every fourth night on the average). The other four stars, (TX Aql, DW Peg, EI Peg, and Z Sex) were all

observed an average of 13 nights, spanning roughly 100 nights. One to three cycles were covered for each star. V564 Oph displayed an unusual asymmetric deep minimum in its light curve. TT Oph has adhered closely to its light elements (61.08^d) over the past 43 years. (8 refs.)

111099 A photometric and spectrographic study of YZ Bootis. M.D.Joner, D.H.McNamara (Dept. of Phys. & Astron., Brigham Young Univ., Provo, UT, USA).
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.433-9 (July 1983).
Photometry of YZ Boo has been secured in the $uvby\beta$ photometric system. A reddening value, $E(b-y)=-0.018^m$, is derived from the photometry. Intrinsic $(b-y)$ and c_1 values used in conjunction with a model-atmosphere grid yields a mean effective temperature, $\langle T_{eff}\rangle=7590$K, and a mean surface gravity, $\langle \log\ g\rangle=3.95$. The metal abundance determined from δm_1 is $[Fe/H]=-0.25$. A mean absolute bolometric magnitude, $\langle M_{bol}\rangle=+1.7$ is inferred from the data. A radius determination by the Wesselink method failed. The radial-velocity data indicate a mean radial velocity of -20 km s^{-1} and a total velocity range of 35 km s^{-1}. YZ Boo is apparently a normal Population I dwarf Cepheid. (15 refs.)

111100 Spectroscopy of six Wolf-Rayet stars: the latest and faintest. P.Massey (Dominion Astrophys. Obs., Herzberg Inst. for Astrophys., Victoria, Canada), P.S.Conti.
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.440-6 (July 1983).
Presents absolute spectrophotometry and classification of six relatively faint galactic Wolf-Rayet (WR) stars for which previous photometry was poor. One of these objects, the heavily reddened infrared source CRL 2179, is the faintest known galactic WR star, with a visual magnitude ~22. Its spectral type is WC10, later than that of any other known Population I WC star. Another faint star, WR 122, has a strong N II emission-line spectrum which is unprecedented: its type is defined by the authors as WN10. The other four stars have typical WR spectra. (25 refs.)

111101 BD+43°1894, a mono-periodic delta Scuti star. A.Yamasaki (Dept. of Earth Sci. & Astron., Univ. of Tokyo, Tokyo, Japan), S.F.Gonzalez, R.Peniche, J.H.Pena.
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.447-50 (July 1983).
New photoelectric observations have been carried out in two different observatories to increase the observing time span of the δ Scuti variable star BD+43°1894. Analysis of these data gives 0.098286^d as the only period of pulsation, making its period one of the shortest among the mono-periodic δ Scuti stars. (5 refs.)

111102 The photometric behavior of FK Comae Berenicis. S.L.Morris, E.F.Milone (Rothney Astrophys. Obs., Univ. of Calgary, Calgary, Canada).
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.376-85 (June 1983).
UBVRI light curves are given of FK Com obtained in February 1981. The light curves and two large flares on this star are examined, and all published light curves of this object are Fourier analyzed and discussed in terms of the current models of this star. An improved period of 2.39960 ± 0.00015 days is also obtained. (20 refs.)

111103 Spectrophotometric observations of CH Cygni in 1980-1982. A.P.Ipatov, B.F.Yudin.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.421-3 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Spectrophotometric observations of CH Cyg in the spectral range 3300-7500 Å with the resolution of 50 Å were carried out in 1980-2. Maximum *UV* radiation was observed in the spring 1982, the bolometric luminosity of the *UV* source not exceeding 10% from the bolometric luminosity of CH Cyg at its quiet period stage. A possibility of explaining the CH Cyg phenomenon in the frame of a single-giant-star model with a hot bright spot in the atmosphere is not rejected by the energetic estimates. (11 refs.)

111104 The intermediate and narrow band photoelectric studies of some delta Scuti stars. C.Ibanoglu, A.Y.Ertan, Z.Tunca, O.Tumer, S.Evren (Ege Univ. Obs., Bornova, Izmir, Turkey).
Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.4, p.261-9 (March 1983).
Intermediate and narrow band photoelectric photometry of the delta Scuti type variables 28 And, 28 Aql, κ Boo and 44 Tau was performed and the physical parameters, average periods were redetermined. The light curves are presented and their variations are discussed. (28 refs.)

111105 Spectral variations in HD 190002: evidence of a companion. G.F.Bisiacchi, C.Firmani, E.de Lara (Inst. de Astron., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico).
Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.4, p.285-8 (March 1983).
Eight medium dispersion (1.1 Å $channel^{-1}$) spectra of HD 190002 are analyzed in the spectral range 4440-4800 Å. The equivalent width and the profile of the C III 4650 Å He II 4686 Å blend shows periodic variability with a period of 8.16 days. The variation of the equivalent width of the line is interpreted as being due to the periodic contribution to the continuum of the WC7 star by a secondary object. (10 refs.)

111106 A photometric study of dwarf novae. J.Echevarria (Univ. of Sussex, Brighton, England), D.Jones.
Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.4, p.301-8 (March 1983).
A catalogue of *UBVRI* photoelectric photometry of dwarf novae available in the literature is presented. A comparison with theoretical colour-colour diagrams from steady state discs is made. A correlation of *V*-magnitude with the depth of the Balmer discontinuity is discussed. (46 refs.)

111107 The radial pulsation modes of the δ Scuti stars, and their nonuniform period distribution. Ts.G.Tsvetkov (Phys. Dept., Sofia Univ., Sofia, Bulgaria).
Sov. Astron. (USA), vol.26, no.6, p.666-72 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1103-14 (Nov.-Dec. 1982).
From Breger's 1979 survey of the observational data for the δ Sct variables, radial pulsation modes are assigned to 83 of these stars. They can pulsate in the four lowest modes; F, $1H$, $2H$, $3H$, and perhaps also in $4H$ and even $5H$. Confirming the author's earlier suggestion, the apparent nonuniformity in the distribution of δ Sct stars both with respect to period and in the period-luminosity diagram may naturally be attributed to pulsation in differing modes. Semiempirical (P,L) relations are derived for the four lowest modes, and the semiempirical and theoretical period ratios are compared. Several statistical relationships are obtained, and in certain cases criteria are proposed for determining the radial-pulsation mode. (32 refs.)

111108 Mapping of chemical elements on the surfaces of Ap stars. I. Solution of the inverse problem of finding local profiles of spectral lines. A.V.Goncharskii, V.V.Stepanov, V.L.Khokhlova, A.G.Yagola (Phys. Dept., Moscow State Univ., Moscow, USSR).
Sov. Astron. (USA), vol.26, no.6, p.690-6 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1146-56 (Nov.-Dec. 1982).
An algorithm is developed for solving the incorrectly stated inverse problem of finding local profiles of spectral lines for a rotating, chemically inhomogeneous star by Tikhonov's regularization method. The program is written in the FORTRAN language and investigated through the solution of model problems. (21 refs.)

111109 WBVR photometry of SS 433: spectra of the 'normal' star and the accretion disk. A.M.Cherepashchuk, A.A.Aslanov, V.G.Kornilov (P.K. Shternberg State Astron. Inst., Moscow, USSR).
Sov. Astron. (USA), vol.26, no.6, p.697-702 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1157-66 (Nov.-Dec. 1982).
WBVR photoelectric photometry of SS 433 is carried out at different phases of the 13-day period (phase $\psi\simeq0.5$ for the 164-day period). The light curves in the WBVR filters are qualitatively similar and the depths of the primary minimum (eclipse of the accretion disk by the 'normal' star) are $O.8^m$, 0.7^m, 0.55^m, and 0.4^m in the W, B, V, and R filters, respectively. The authors bring out the 13-day periodic variability in the J, H, and K filters (using published data). The interstellar absorption is determined for SS 433:$A_v=7.4^m$-8.3^m. Drawing on infrared observations, the authors construct unreddened spectra of the 'normal' star and the accretion disk at phases $\psi=0.5$ and 0 of the 164-day precession period. For $A_v=7.4^m$-8.3^m the spectrum of the 'normal' star has a color temperature $T_c=13000$-43000K. The mass of the 'normal' star is $m_v>10\ M_\odot$. The 'normal' star fills its Roche lobe and outflow takes place in the thermal time scale of relaxation. The spectrum of the projection of the accretion disk in the optical range is bluer than that of the 'normal' star and for $A_v=7.85^m$ it can be approximated satisfactorily by a Planck function at $T\geq50000$K. The bolometric luminosity of the disk exceeds 10^{40} erg/sec. The appearance of collimated relativistic ejections perpendicular to the disk plane is evidently connected with supercritical accretion of matter onto the relativistic object in the massive close binary system. The analogy between the processes taking place in the accretion disk in the SS 433 system and the processes observed in the galactic nuclei and quasars is pointed out. (28 refs.)

97.60 LATE STAGES OF STELLAR EVOLUTION
(inc. black holes)

97.60B Supernovae

111110 On the frequency of supernova flares in Sc galaxies. R.G.Mnatsakanyan (Byurakan Astrophys. Obs., USSR).
Astrophysics (USA), vol.18, no.4, p.321-8 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.563-73 (Oct.-Dec. 1982).
The mean frequency of supernova explosions in Sc galaxies is determined by a method used to calculate the mean frequency of flares of flare stars in star aggregates (Ambartsumyan 1969). The mean time interval between two successive supernova explosions in one Sc galaxy brighter than 12.0^m is 48 years. It has not been possible to find clear dependence of the frequency of supernova explosions on the luminosity of the parent galaxy for the considered group of galaxies. (15 refs.)

111111 Anomalous reddening of supernovae. M.Joeveer (Inst. of Astrophys. & Phys. of Atmosphere, Acad. of Sci., Estonian SSR).
Astrophysics (USA), vol.18, no.4, p.328-31 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.574-9 (Oct.-Dec. 1982).
A study is made of the correlation between the color excesses E_{B-V} and the distorted (by absorption) absolute magnitudes M_{pg} of supernovae in the complex around the Virgo cluster of galaxies. It is shown that type I supernovae with different reddenings have equal $M0_{pg}$ only when allowance is made for the absorption of light in accordance with the anomalous relation $A_{pg}=1.8E_{B-V}$. After allowance for absorption in accordance with this relation moderately reddened ($E_{B-V}<0.5$) type I supernovae in spiral galaxies are almost as good standard candles as type I supernovae in elliptical galaxies. (17 refs.)

111112 Cosmological estimate of the age of stars exploding as Type I supernovae. I.S.Shklovskii (Space Res. Inst., Acad. of Sci., Moscow, USSR).
Nature (GB), vol.304, no.5926, p.513 (11 Aug. 1983).
There is evidence to suggest that quasars are active nuclei of galaxies most of which formed at $z\sim2.5$ when the age of the Universe was 1000-2000 Myr. During the same period of time the intergalactic gas should have formed in clusters, with a Fe abundance lower by a factor of 3 than that of oxygen. It is argued that the evolution time of the stars responsible for the synthesis of

Fe nuclei (apparently Type 1 supernovae) should be ~1500 Myr and their masses small, ~1.7-1.5 $M_{\odot}$. (7 refs.)

111113 Discovery of an IR echo from a supernova dust cloud. J.R.Graham, W.P.S.Meikle, M.J.Selby (Dept. of Phys., Imperial Coll. of Sci. & Technol., London, England), D.A.Allen, A.Evans, G.Pearce, M.F.Bode, A.J.Longmore, P.M.Williams.
Nature (GB), vol.304, no.5928, p.709-10 (25 Aug. 1983).
The authors have obtained IR light curves for SN 1982e in NGC 1332 covering 100-250 days after its discovery. It is shown that the IR radiation is due to heated dust. No evidence has been found for grain condensation in the SN ejecta. In fact, the light curves reveal that the IR emission originates from a pre-existing circumstellar dust cloud and is produced by an 'echo' of the UV and visible pulse of the SN. (18 refs.)

111114 The Local Group supernova rate. S.Van Den Bergh (Dominion Astrophys. Obs., Herzberg Inst. of Astrophys., Victoria, Canada).
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.388-90 (June 1983).
Observations of distant spirals would lead one to expect a total of ~6 $(H/50)^2$ supernovae per century in Local Group galaxies other than the Milky Way. In fact only one such subject (S And) has been discovered during the last 100 years. Available evidence on historical galactic supernovae is roughly consistent with the supernovae rate derived from distant spirals. It is therefore tentatively concluded that the number of Local Group Supernovae may have been unusually low during the last century or that some of them have unexpectedly remained undiscovered. (13 refs.)

111115 Supernova outburst in a circumstellar dusty envelope. V.A.Okorokov.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.353-7 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
The appearence of a supernova outburst in a circumstellar dusty envelope is studied. Spectra of emergent radiation at various stages of the supernova flash are constructed. The influence of the envelope on the probability of supernova detection is estimated. For a mass-loss rate at the supergiant stage of $M=10^{-3}$ $M_{\odot}$/yr the probability to detect the flash decreases by more than an order of magnitude. (14 refs.)

111116 Line profiles and a model of the envelope of the type II supernova SN 1970g. N.N.Chugai (Astron. Council, Acad. of Sci., USSR).
Sov. Astron. (USA), vol.26, no.6, p.683-90 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1134-45 (Nov.-Dec. 1982).
Profiles of the Hα and Na Iλ 5892 lines, which are observed in the spectrum of SN 1970g, are calculated. The expansion velocity V_c at the photosphere level, which proved to be considerably lower than the radial velocity of the absorption minima, is found from a comparison of calculations and observations. The velocity V_c decreases with time. The kinematic radius $V_c t$ of the photosphere reaches a maximum almost simultaneously with the photometric radius on about the 10th day after the end of the 'plateau' phase. The value of n_e, which does not depend on the adopted distance to the supernova, is determined from the Hα profile. The mass of ionized hydrogen in the envelope (0.1-0.2 $M_{\odot}$), the oxygen mass (0.03-0.2 $M_{\odot}$), and the sodium mass (10^{-4} $M_{\odot}$) are estimated. The distribution of ionized hydrogen in the envelope of Sn 1970g based on the velocities has a concentration maximum in the vicinity of $V=1400$ km/sec for the time of 92 days after maximum light. The density of matter in the envelope declines with an increase in velocity, at least in the velocity range $V>1500$ km/sec. (17 refs.)

97.60G Pulsars

111117 On the radio pulse emission mechanism of PSR 1133+16: simultaneous dual-frequency high time resolution observations. V.Boriakoff (Nat. Astron. & Ionosphere Center, Cornell Univ., Ithaca, NY, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.687-701 (15 Sept. 1983).
The microstructure of PSR 1133+16 (a pulsar which has two peaks in the average pulse profile) has been studied simultaneously at 318 and 196.3 MHz with the 305 m Arecibo radio telescope. A cross-correlation study shows that the microstructure is broad band in this frequency range, and that it follows the interstellar plasma dispersion relation. That is, the emission of a micropulse is simultaneous at 318 and 196.3 MHz at the source. However, the subpulses do not follow the dispersion line but instead follow the $\nu^{-0.26}$ dependence of the average profile peak separation with frequency. Implications of these observations for current theories are discussed. (33 refs.)

111118 Implications of the millisecond pulsar for neutron star models. S.L.Shapiro, S.A.Teukolsky, I.Wasserman (Center for Radiophys. & Space Res., Cornell Univ., Ithaca, NY, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.702-7 (15 Sept. 1983).
Examines the constraints imposed by the high spin rate of PSR 1937+214 on the masses and radii of nonrotating neutron stars that can be spun up to such a short period. Assuming uniform rotation, it is found that none of the currently viable nuclear equations of state can be ruled out. However, the discovery of a single pulsar with period $\lesssim 0.5$ ms would rule out all current equations of state. Assuming that PSR 1937+214 was spun up uniformly from a nonrotating progenitor requires that the maximum mass of a nonrotating star in general relativity cannot exceed 12.5 $M_{\odot}$, independent of any knowledge of the equation of state. This limit decreases linearly with the shortest known period of a pulsar. (38 refs.)

111119 On the decay of gamma-quanta of curvature radiation near a pulsar surface. V.V.Usov, A.E.Shabad.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.401-4 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
It is shown that when the magnetic field strength on the surface of a pulsar exceeds 0.2 B_{cr} ($B_{cr}=m^2c^3/e\hbar$) a considerable number of curvature photons with the electric field vector orthogonal to the plane in which the external magnetic field and the photon wave vector lie decay before reaching the threshold of pair creation. Polarization observations of the pulsar curvature γ-radiation may present a possibility of judging the value of the magnetic field near the pulsar surface. (22 refs.)

97.60J Neutron stars

111120 Structure of neutron star envelopes. E.H.Gudmundsson, C.J.Pethick, R.I.Epstein (Nordita, Copenhagen, Denmark).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.286-300 (1 Sept. 1983).
Investigates the envelopes of nonmagnetic neutron stars using the best available opacities and equation of state. The temperature at the inner boundary of the envelope, T_b, is found to be very nearly a universal function of the parameter T_s^4/g_s, where T_s is the effective surface temperature, and g_s is the surface gravity of the neutron star. This result is used to derive a number of other scaling relations, to investigate the effects of general relativity on the thermal structure of the envelope, and to compare envelope calculations by different workers. (61 refs.)

111121 Analytic neutron stars in general relativity: exact solutions for the non-homogeneous charged model. J.M.Ibanez Cabanell (Dept. de Mecanica y Astron., Facultad de Matematicas, Burjasot, Valencia, Spain).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.133-43 (July 1983).
Extends the so-called Adams' (1974) method to the non-homogeneous charged model of neutron stars. Numerical applications are compared with results obtained for a given equation of state. (22 refs.)

111122 Normal and pion-condensed states in neutron star matter in a relativistic field theory constrained by bulk nuclear properties. I. N.K.Glendenning, B.Banerjee, M.Gyulassy (Lawrence Berkeley Lab., Univ. of California, Berkeley, CA, USA).
Ann. Phys. (USA), vol.149, no.1, p.1-21 (Aug. 1983).
A theory of isospin asymmetric matter and of neutron star matter in particular, which is compatible with bulk nuclear properties, is formulated in the framework of a relativistic field theory and solved in the mean field approximation. The self-consistent conditions defining the σ-, ω-, π-, and ρ-fields are derived for the normal and the pion-condensed states in explicit form for asymmetric matter, which is in chemical equilibrium, and with prescribed total charge. (12 refs.)

111123 Normal and pion-condensed states in neutron star matter in a relativistic field theory constrained by nuclear bulk properties. II. N.K.Glendenning, P.Hecking, V.Ruck (Lawrence Berkeley Lab., Univ. of California, Berkeley, CA, USA).
Ann. Phys. (USA), vol.149, no.1, p.22-43 (Aug. 1983).
For pt.I see ibid., vol.149, no.1, p.1-21 (1983). A relativistic field theory of isospin asymmetric matter and of neutron star matter in particular, which is compatible with nuclear matter bulk properties, was formulated in Part I of this series and treated in mean-field approximation. The self-consistent solutions include the σ, ω, and ρ-fields for both the normal and pion-condensed states. The bulk properties of nuclear matter such as saturation density and energy, compressibility and asymmetry energy impose rather stringent restrictions on meson-nucleon coupling constants and the parameters of the nonlinear interactions in the σ-model. The numerical results include the equation of state, particle densities as functions of charge and baryon density and the composition of a neutron star. Based on these results, the authors discuss neutron star cooling for various equations of state. (18 refs.)

111124 Thermal origin of neutron star magnetic fields. R.D.Blandford, J.H.Applegate, L.Hernquist.
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.1025-48 (Sept. 1983).
It is proposed that magnetic field arises naturally in neutron stars as a consequence of thermal effects occurring in their outer crusts. The heat flux through the crust can give rise to a possible thermoelectric instability in the solid crust which causes horizontal magnetic field components to grow exponentially with time. However, in order for the thermally driven growth to exceed ohmic decay, either the electron collision time must exceed existing estimates by a factor ~3 or the surface layers comprise helium. A second instability is possible if the liquid phase that lies above the solid crust also contains a horizontal magnetic field. If either of these two instabilities develops the field will quickly grow to a strength of $\sim 10^{12}$G, where the instabilities become non-linear. Further growth will saturate when either the magnetic stress exceeds the lattice yield stress or the temperature perturbations become non-linear, both of which occur at a subsurface field strength of $\sim 10^{14}$G; the corresponding surface field strength is $\sim 10^{12}$G. Further evolution of the magnetic field should lead to long-range order and yield neutron star magnetic dipole moments $\sim 10^{30}$G cm^3, comparable with those observed. (75 refs.)

97.60L Black holes

111125 The dynamics of dissipatively heated spherical accretion. E.T.Scharlemann (Dept. of Astron., Columbia Univ., New York, NY, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.279-85 (1 Sept. 1983).
The dynamical equations that describe dissipatively heated spherical accretion onto a black hole are developed, without the customary assumption of equipartition between the magnetic energy density and the gravitational potential energy density. Instead, the (somewhat arbitrary) assumption is made that, after averaging over a spherical surface, the local electric field associated with the magnetic field dissipation is a fixed fraction of the Alfven velocity times the radial field strength. A dynamically significant radial stress term appears in the momentum equation; the stress is shown also to be required by energy conservation, irrespective of the electric field assumption. The radial stress gives rise to an instability of the flow, characterized by density and temperature fluctuations of opposite sign. The instability has implications for the variability and Comptonization of the luminosity of quasars and active galactic nuclei. (10 refs.)

111126 Neutrino emission from black holes. F.Giovannelli (Inst. of Space Astrophys., CNR, Frascati, Italy), S.Karakula, W.Tkaczyk.
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.126-9 (Aug. 1983).
Spherically accretion of matter onto massive objects (Schwarzschild black holes) is one of the processes responsible for the heating of a proton plasma up to ultra-relativistic temperatures. Using the neutrino and antineutrino energy production spectra in a relativistic plasma (Giovannelli et al., 1983) in the temperature range 10^{11}-10^{13}K, the authors derive the expected neutrino and antineutrino energy spectra from matter accreting spherically onto massive objects. From the computed spectra, the luminosity of a black hole of 10 $M_{\odot}$ and with mass accretion rate $M=10^{-8}$ $M_{\odot}$/yr and the emissivity of the same object for the same Mach's numbers are found. (14 refs.)

97.80 BINARY AND MULTIPLE STARS

(inc. extrasolar planetary systems)

111127 Discovery of a massive unseen star in LMC X-3. A.P.Cowley (Univ. of Michigan, Ann Arbor, MI, USA), D.Crampton, J.B.Hutchings, R.Remillard, J.E.Penfold.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.118-22 (1 Sept. 1983).
Spectroscopic observations of the optical counterpart of LMC X-3 show it to be a spectroscopic binary in the Large Magellanic Cloud with an orbital period of 1.70 days. The B3 main-sequence primary has a large radial velocity amplitude ($K=235\pm11$ km s^{-1}) indicating a mass function of 2.3 $M_\odot$. LMC X-3 is an extremely luminous and variable X-ray source, but no 1.7 day X-ray periodicity has been detected. The lack of optical and X-ray eclipses limits the inclination to $i=<70°$ and implies a mass for the unseen star of $M_x>9.0$ $M_\odot$, if the B star has a normal mass. The system now appears to be the strongest evidence for the existence of a stellar mass black hole and is the first extragalactic example. (18 refs.)

111128 A new look at BE Ursae Majoris. D.Crampton, A.P.Cowley, J.B.Hutchings (Dominion Astrophys. Obs., Herzberg Inst. of Astrophys., Victoria, BC, Canada).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.202-5 (1 Sept. 1983).
The radial velocity and light curve of BE UMa have been studied to determine the physical parameters of the stellar components. The authors find that the primary is a very hot subdwarf which has a large heating effect on a cool secondary, whose magnitude and radius both indicate that it is an evolved subgiant. (10 refs.)

111129 RW Tauri as a weak W Serpentis star. M.J.Plavec, J.J.Dobias (Dept. of Astron., Univ. of California, Los Angeles, CA, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.206-13 (1 Sept. 1983).
The short-period classical Algol system RW Tauri was observed with the *IUE* satellite in 1982 August and with the ITS scanner of Lick Observatory between 1982 August and October. *IUE* observations in the total eclipse showed weak excess continuous radiation in the LWR camera, while the SWP camera revealed several emission lines typical for the W Serpentis stars and of about the same strength as in U Cephei. Combined *IUE* and optical scans gave for the primary star: $T_{\rm eff}=11750$K, log $g=4.2$, spectral type of the cool component as K0 III, color excess $E(B-V)=0.14$ mag, and distance to the system 270 pc. (25 refs.)

111130 HEAO 1 high-energy X-ray observations of Centaurus X-3. S.K.Howe, F.A.Primini, M.W.Bautz, F.L.Lang, A.M.Levine, W.H.G.Lewin (Dept. of Phys., MIT, Cambridge, MA, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.678-86 (15 Sept. 1983).
The results of observations of Cen X-3 made with the UCSD/MIT High-Energy X-Ray and Low-Energy Gamma-Ray Experiment aboard the HEAO 1 satellite are presented. The observations covered two $\sim50^d$ time intervals spanning ~1 yr. The results include the detection of both high- and low-intensity states, measurement of the pulsation period and its rate of change over the entire second 50^d interval, detection of X-ray pulsations above ~38 keV, and measurement of the X-ray spectrum above ~12 keV as a function of pulse phase. (37 refs.)

111131 Spectrophotometric studies of star HD 157978. M.A.Hamdy (Helwan Obs., Cairo, Egypt), S.Abou Elazm.
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.1-3 (July 1983).
Examination of the stellar spectrum of this star reveals that it has a composite spectrum. It could be classified as (A7V+G5V). It contains three forbidden (Fe II) lines which are of the essential features of η Carinae stars. The spectrum also contains H, He I, Fe II, Mn I, Ti II, and other different lines. The K-line seems to be sharp double line while other lines appear single ones which suggest early component may be double. This also seems to be true according to radial velocity measurements. (4 refs.)

111132 Apsidal motion in the eclipsing binary AS Cam. Kh.F.Khaliullin, V.S.Kozyreva (Sternberg Astron. Inst., Moscow Univ., Moscow, USSR).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.115-22 (July 1983).
Multi-colour WBVR photoelectric observations of the eclipsing binary AS Cam have been carried out and the photometric elements, absolute dimensions, and the angular velocity of a periastron motion (ω_0Rdb$_s$) are determined. The obtained value of $\omega_{\rm obs}$ is almost three times smaller than that theoretically predicted. (18 refs.)

111133 The angular momentum of eclipsing binaries. R.F.Sistero, S.Marton (Obs. Astron., Univ. Nacional, Cordoba, Argentina).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.165-70 (July 1983).
The angular momentum-mass relationship for 1048 eclipsing binaries is presented. (13 refs.)

111134 Detection of a stellar prominence of the K supergiant 32 Cyg. K.-P.Schroder (Hamburger Sternwarte, Univ. Hamburg, Hamburg, Germany).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.L16-18 (Aug. 1983).
A sequence of high-resolution IUE spectra taken around the 1981 eclipse of 32 Cyg B has been used for determining light curves at various UV wavelengths. The first detection of a stellar prominence of the K supergiant, seen as transient absorption of the B star continuum flux, is reported. The absorption mechanism is most probably Rayleigh scattering which follows from the wavelength dependence of optical depths $\tau_\nu\sim\nu^{5.5}$. The prominence has a typical column density of $N_H=2.8\times10^{24}$ cm^{-2}, α linear extension perpendicular to the line of sight of about 30 $R_\odot$ and an apparent height of 15 $R_\odot$ above the limb. (19 refs.)

111135 A study of UV spectra of ζ Aur/VV Cep stars. IV. System parameters and mass-loss of δ Sge. D.Reimers, K.-P.Schroder (Hamburger Sternwarte, Univ. Hamburg, Hamburg, Germany).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.241-6 (Aug. 1983).
The orbital elements of the δ Sge system are improved using new radial velocity measurements. A distance of 170 pc is determined with the assumption that the companion is a main-sequence star with $T_e=10500$K (ca. B9) as found from IUE fluxes. Using circumstellar Fe II absorption lines in the UV spectrum of the B star companion, a mass-loss rate of 2×10^{-8} $M_\odot$yr^{-1} has been found for the M2 II primary. Evidence for an accretion disk around the B star fed by the M giant wind and a shock front moving with the B star is briefly discussed. (26 refs.)

111136 HD 134518: a main-sequence detached or a semi-detached eclipsing binary?. G.Russo (Capodimonte Astron. Obs., Naples, Italy).
Astron. Nachr. (Germany), vol.304, no.3, p.133-6 (1983).
Analyzes Przybylsky's (1981) photometric observations of HD 134518, an eclipsing binary with a period of 1.15 days and a β Lyrae type light curve. Performing a grid of solutions with different assumed values of the mass ratio by means of the Wilson-Devinney method the author has determined the photometric elements of this variable, which shows an extremely low mass ratio ($q=m_c/m_h=0.06$) and appears to be a semi-detached system. The discrepancies between the Wilson-Devinney solution and the Wood solution are pointed out. (12 refs.)

111137 A redetermination of the orbit of HD 123299. E.W.Elst (Koninklijke Sterrenwacht van Belgie, Brussel, Belgium), B.Nelles.
Astron. & Astrophys. Suppl. Ser. (France), vol.53, no.2, p.215-17 (Aug. 1983).
Radial velocity measurements of HD 123299 are presented. All available data are analysed and lead to improved orbital elements. (7 refs.)

111138 Preliminary 1983 photometry of HD 174429 (PZ tel.). J.L.Innis, D.W.Coates, T.T.Moon, K.Thompson (Dept. of Phys., Monash Univ., Clayton, Victoria, Australia).
Inf. Bull. Variable Stars (Hungary), no.2378, p.1-4 (4 Aug. 1983).
Reports photoelectric BV photometry during May and June 1983 of the RS Canum Venaticorum star HD 174429 (KO Vp). (8 refs.)

111139 Some observations of the central star of the bipolar planetary nebula NGC 2346. A.Purgathofer, A.Schnell (Inst. for Astron., Univ. of Vienna, Vienna, Austria).
Inf. Bull. Variable Stars (Hungary), no.2379, p.1-3 (8 Aug. 1983).
The authors report UBV photometry of the central star of NGC 2346 between April 1982 and January 1983. Between March and October 1982 the light curve was nearly sinusoidal, with maxima and minima in V-light of about 11.5 and 14.0 mag. However, since November 1982 the brightness of the star has decreased throughout the light curve, and a very deep and wide minimum has developed; in January 1983 the star varied between about magnitude 12.5 and magnitude 15.0, and the central phase of the eclipse extended from $\phi=0.7$ to $\phi=0.3$. (5 refs.)

111140 Local regularization of the magnetic-binary problem. A.G.Mavraganis (Nat. Tech. Univ., Athens, Greece).
Celestial Mech. (Netherlands), vol.30, no.3, p.219-24 (July 1983).
The singularities in a magnetic-binary system are regularized separately by changing both the coordinates and the time. It is shown why, in this problem, it is more efficient to relate the geometric transformation to the rescaling of time. (5 refs.)

111141 ϵ Aurigae. M.Parthasarathy, D.L.Lambert.
I.A.U. Circ. (USA), no.3857, 1 pp. (29 Aug. 1983).
Observations of ϵ Aurigae during totality show variations in the strength of the K I 770 nm resonance line: W(λ) was 0.055 nm between December 1982 and March 1983, and 0.043 nm between April and July 1983. The Hα line is broad and the emission in the wings has disappeared. (1 ref.)

111142 4U 1543−45. R.J.Blissett, H.Pedersen, M.Veron, P.Veron, H.-E.Schuster.
I.A.U. Circ. (USA), no.3858, 1 pp. (6 Sept. 1983).
It is reported that an EXOSAT observation on 1983 August 28 located the transient X-ray source 4U 1543−45 at $\alpha=15^h43^m34^s$, $\delta=-47°31.1'$ (equinox 1950.0). The 2 to 10 keV spectrum is unusually soft, with a characteristic temperature of about 1.7 keV. A possible optical counterpart of this X-ray source has been identified, namely a 15th-magnitude star at $\alpha=15^h43^m33.9^s$, $\delta=-47°30'54''$ (equinox 1950.0); this star has recently brightened by about 1 magnitude. Low dispersion spectra obtained on September 2 and 3 show emission lines of He I, He II and N III. (2 refs.)

111143 A 0538−66. J.Menzies, I.Howarth.
I.A.U. Circ. (USA), no.3858, 1 pp. (6 Sept. 1983).
It is reported that the LMC recurrent X-ray transient A 0538−66 appears to have become active again. Spectrograms obtained on 1983 August 9 show weak emission lines at Hβ and Hγ, and a strong, double-peaked emission line at He II 469 nm. An IUE observation on August 26 shows emission lines at N V 1224 nm, C IV 155 nm and He II 164 nm. (1 ref.)

111144 A study of the binary system 58 Persei. D.L.Harmer, D.J.Stickland, C.Lloyd, C.F.W.Harmer, C.D.Pike (Royal Greenwich Obs., Hailsham, England), D.Croft.
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.927-34 (Sept. 1983).
The spectroscopic (and astrometric) binary 58 Persei has been observed at optical wavelengths and with IUE. The system is shown to consist of a mid-B-type main-sequence star and a late-G-type supergiant at a distance of 320 pc. (27 refs.)

111145 CPD −62° 1837: a K0 III+Mira binary system?. J.W.Menzies, R.M.Catchpole, P.A.Whitelock (South Africa Astron. Obs., Cape Town, S Africa).
Observatory (GB), vol.103, no.1055, p.195-8 (Aug. 1983).
From new optical and infrared observations of the Trapezium-like system CPD −62° 1837, it is shown that the faintest star (C), of spectral type M3 III, is not physically associated with the other two. Stars A and B are at the same distance and have the same radial velocities to within the errors of measurement. One of these stars (B) is a Mira variable with a period of 320 days. (7 refs.)

111146 Spectroscopic binary orbits from photoelectric radial velocities. LI. 30 Vulpeculae. R.F.Griffin (Cambridge Obs., Cambridge, England).
Observatory (GB), vol.103, no.1055, p.199-203 (Aug. 1983).
Presents an orbital analysis of this bright late-type giant star derived from four Lick observations (1918-21) and 61 observations from the period 1969-83. (30 refs.)

111147 A photometric orbit for the eclipsing binary AG Phoenicis. M.A.Cerruti (Inst. de Astron., Fisica del Espacio, Buenos Aires, Argentina).
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.347-53 (June 1983).
In each of the UBV bandpasses about 1760 observations define for the first time the photoelectric light variation of the binary system AG Phe. A consis-

tent set of elements is derived in the framework of the classical model. The system would be a well-detached binary consisting of two normal A9 and K0 main-sequence components. (15 refs.)

111148 Narrow- and intermediate-band Hα and O I λ7774 photometry and Reticon spectroscopy of SX Cassiopeiae. E.F.Guinan (Dept. of Astron., Villanova Univ., Villanova, PA, USA), S.Tomczyk, D.J.Turnshek.
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.364-7 (June 1983).
The complicated 36.57-day eclipsing binary SX Cas was observed on eight nights during February and March 1979 with pairs of intermediate- and narrow-band filters centered on the wavelengths of the Balmer Hα line and the O I λ7774 triplet. In addition, a Reticon spectrum, covering a wavelength range of 4750 Å to 7700 Å, was obtained during September 1979; this shows strong Hβ and Hα emission lines as well as showing absorption features of the K-giant component of the system. Strong Hα emission is found at all the orbital phases sampled. The emission is consistent with the presence of significant amounts of circumstellar and circumbinary gas. (8 refs.)

111149 Identification of the soft X-ray source H 1011$-$47 (=E 1013$-$477): a new magnetic variable?. K.O.Mason (Mullard Space Sci. Lab., Dorking, England), F.A.Cordova, J.Middleditch, G.A.Reichert, S.Bowyer, P.Murdin, D.Clark.
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.370-5 (June 1983).
A variable, blue, emission-line star is identified as the probable counterpart of the HEAO-1 soft X-ray source H 1011$-$47 on the basis of an improved position derived with the Einstein satellite. The star varies between magnitudes 16.7 and 17.7 on a time scale of ~100 minutes and by as much as 0.6 magnitude on a time scale of a few minutes. The spectrum exhibits strong, broad optical emission lines of hydrogen, He I, He II, and Ca II, and strong ultraviolet emission lines of C IV and Si IV. These characteristics suggest that the star most probably belongs to the AM Her class of magnetic cataclysmic binary. (6 refs.)

111150 Ultraviolet observations of the transient X-ray sources A 0535+26 and A 0620$-$00. Chi-Chao Wu, R.J.Panek, A.V.Holm, M.Schmitz (Computer Sci. Corp., Silver Spring, MD, USA), J.H.Swank.
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.391-7 (June 1983).
A 0535+26 (HDE 245770) was observed by the ANS in September 1975 and March 1976 when it was at the X-ray low state. Fifty-eight early-type stars which lie within 10° of HDE 245770 were also observed by the ANS, and these stars were used to derive a localized extinction curve. An $E(B-V)=0.72$ is derived for HDE 245770. A 0620$-$00 was observed by the ANS in March 1976. Twenty-five early-type stars were used to establish a localized extinction curve and an $E(B-V)=0.35$ was derived. The dereddened continuum can be described by a combination of 60% $T=18000$K black body and 40% F_ν=constant spectra. (30 refs.)

111151 Orbits of 15 visual binaries. G.A.Starikova.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.353-9 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
From available published data and from new observations the revised orbits of 15 visual binary stars are obtained. The new orbits are in better agreement with the observations. (1 ref.)

97.90 OTHER TOPICS IN STELLAR ASTRONOMY

111152 On the evolution of massive zero-metal stars. V.Castellani, A.Chieffi, A.Tornambe (Inst. for Space Astrophys., CNR, Frascati, Italy).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.249-55 (1 Sept. 1983).
The evolution of zero-metal stars of 10, 15, and 25 $M_\odot$ has been followed through the core H burning and the core He burning phases to the phase of C ignition. It is found that such stars fail to reach the red giant region, burning both H and He at large effective temperature (log $T_e=4.5$). Variations in the original amount of He in the range $0.20<Y<0.30$ only marginally affect the structures of the stars. Zero-metal stars develop peculiarly small H exhausted regions, with larger electron degeneracy in comparison with Population II stars. The impact of supernovae from those stars is briefly discussed in terms of chemical pollution by Population III. (19 refs.)

111153 An investigation of faint stars in a region of the Magellanic Stream. M.T.Bruck, M.R.S.Hawkins (Dept. of Astron., Univ. of Edinburgh, Edinburgh, Scotland).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.216-22 (Aug. 1983).
Star counts to 20.5^m in B have been performed on UKST plates using the COSMOS automatic measuring machine of an extended area in the Magellanic Stream. No surplus of stars has been found in the region of maximum HI density. Excess stars to 20.5^m are expected to consist of intermediate age objects. Their evident scarcity in the Magellanic Stream can be explained if the supposed encounter of the Magellanic Clouds with the Galaxy occurred before or at the time of the birth of the intermediate age stars ($\sim 3\times10^9$ yr ago). (17 refs.)

111154 Can Population III stars generate primordial helium?. J.R.Bond, B.J.Carr (Inst. of Astron., Cambridge Univ., Cambridge, England), W.D.Arnett.
Nature (GB), vol.304, no.5926, p.514-15 (11 Aug. 1983).
Only stars with masses in excess of ~200 $M_\odot$ can generate a cosmologically significant amount of helium without overproducing either metals or radiation. Such very massive objects (VMOs) would also leave a large number of black hole remnants. Stellar evolution calculations show that the helium-rich envelope of VMOs could undergo explosive ejection. A viable model of primordial helium synthesis is described which can be constructed after recombination, providing heavy elements are not dredged up and ejected at the same time. (12 refs.)

98.20 STELLAR CLUSTERS AND ASSOCIATIONS

111155 The ellipticities of globular clusters and the second parameter problem. J.Norris (Mount Stromlo & Siding Spring Obs., Res. School of Phys. Sci., Australian Nat. Univ., Canberra, Australia).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.245-8 (1 Sept. 1983).
For globular clusters with abundances in the range $-1.9\leq[\mathrm{Fe/H}]\leq-1.4$, which brackets those of the classic 'second parameter' trio M13-M3-NGC 7006, a correlation appears to exist between the Mironov horizontal branch parameter $B/(B+R)$ and the apparent cluster ellipticities, in the sense that there are no clusters with red horizontal branches and higher than average ellipticities. The correlation is significant at the 4.0% level, and offers support for the hypothesis that angular momentum is a parameter affecting horizontal-branch morphology. (22 refs.)

111156 The kinematics of globular clusters in the large Magellanic cloud. K.C.Freeman (Mount Stromlo & Siding Spring Obs., Private Bag, Woden, Australia), G.Illingworth, A.Oemler,Jr..
Astrophys. J. (USA), vol.272, no.2, pt.1, p.488-508 (15 Sept. 1983).
Velocities are determined for 35 globular clusters in the LMC. These data are combined with data from other sources to give velocities for 59 clusters ranging in age from $\sim10^8$ to $\sim10^{10}$ yr. A study of the kinematics-age relation for the LMC globular cluster system is performed. The young clusters form a flattened system having a low line-of-sight velocity dispersion, an amplitude of their rotation of 37 ± 5 km s^{-1}, a galactocentric systemic velocity of 40 ± 3 km s^{-1}, and a line of nodes in position angle 1°±5°, consistent with that found from previous kinematical and photometric studies. The older clusters are also flattened to a disklike system with an intrinsic line-of-signt dispersion of only 17 km s^{-1}, and a rotation amplitude of 41 ± 4 km s^{-1}. Surprisingly, however, both the systemic velocity at 26 ± 2 km s^{-1}, and the position angle of the line of nodes at 41°±5 are very significantly different for the older clusters. This enigmatic situation resisted all attempts at a solution. While the number of clusters is small, it was striking to note that even the oldest clusters in the LMC appeared to lie in a highly flattened disklike system with a z scale height $z_0\sim0.5$ kpc at $r\approx3°\approx3$ kpc. There is no evidence for a kinematic halo population among the globular clusters in the LMC. (51 refs.)

111157 Magnitudes and colours of stars of central part of globular cluster M15. N.M.Spassova (Dept. of Astron., Bulgarian Acad. of Sci., Sofia, Bulgaria).
C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.5, p.553-6 (1983).
The BV magnitudes of 206 stars in the central part of cluster M 15 are listed. Four V-plates (103 aD+6611) and three B short-exposure plates (ORWO ZU21+GG13, 103aO+GG13), taken in the Cassegrain focus of the Schemaha 2 m (7″/m) and Bulgaria 2 m (12.8″/m) telescopes, were measured on an iris photometer at Pulkovo Observatory (USSR). Photoelectric and photographic standards were used. A comparison of the author's magnitudes with the standard ones is shown. The author's standard observations involved a mean error of ±0.062(V), ±0.055(B), ±0.061(B-V). All stars brighter than 14.90 (V) and well-resolved on the short-exposure V-plates were measured. At $R<12''$ the star clustering makes iris measurements impossible. In the area of $12''<R<2'.5$, 223 stars were measured. A comparison of the magnitudes obtained on different plates revealed a mean error of ±0.044 (V) and ±0.026 (B) respectively. (10 refs.)

111158 S stars in ω Centauri. T.L.Evans (South African Astron. Obs., Cape Town, S Africa).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.975-84 (Sept. 1983).
The ZrO band at 6473 Å has been found in 10 of the 12 stars previously found to have TiO bands, indicating that these are MS or early S stars. The stars also show strong metal lines and in particular strong Ba II λ4554, in common with hotter fainter stars which are also found to lie to the red (cool) side of the giant branch of ω Cen in the I, V-I diagram. These stars are much fainter than MS stars in the Magellanic Clouds and are not associated with carbon stars as the latter are. It is likely that they represent the top of the range of metal abundance in ω Cen and that the strong Ba II and ZrO features result from a primordial excess of s-process elements. (48 refs.)

111159 Globular clusters and the early chemical history of galactic halos. D.S.De Young, K.Lind, S.E.Strom (Kitt Peak Nat. Obs., Tucson, AZ, USA).
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.401-5 (July 1983).
Calculations presented suggest that ejecta from evolved massive stars in globular clusters could play a significant role in the early chemical evolution of the spheroidal component of galaxies. In the case of the M87 globular cluster system, the yield from massive cluster members, assumed drawn from a Salpeter initial mass function, can supply protogalactic gas of mass 2×10^{11} $\mathfrak{M}_\odot$ with heavy elements sufficient to produce the observed mean metal-to-hydrogen ratio of $Z=10^{-2}$ $Z_\odot$ for the outer halo stars of M87. For initial mass functions with a greater proportion of massive stars, the yield is even larger. (20 refs.)

111160 Detectability of globular cluster systems in distant galaxies. W.E.Harris (Phys. Dept., McMaster Univ., Hamilton, ON, Canada).
Publ. Astron. Soc. Pac. (USA), vol.95, no.569, p.406-10 (July 1983).
A simple modeling procedure is used to describe the appearance of distance globular cluster systems viewed against background fields at various limiting magnitudes. The 'detectability' of such cluster systems, as a function of magnitude and distance, is described numerically under conditions where the background consists of (a) only field stars, or else (b) all types of images (stellar and nonstellar) together. If faint star/galaxy image classification can be successfully carried out to $B_J(\text{lim})\sim26$ (either from space or from ground-based telescopes with modern CCD detectors), the cluster systems around giant elliptical galaxies should be plainly detectable to distances approaching 100 Mpc. (15 refs.)

111161 The spectroscopic parallax of Stock 14. M.P.FitzGerald, M.L.Miller (Astron. Program, Univ. of Waterloo, Waterloo, Canada).
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.361-3 (June 1983).
The spectroscopic parallax of Stock 14 is determined from MK classification of the 14 brightest stars. Of these, two are spectroscopic nonmembers and one is the supergiant V810 Cen. The authors find a mean colour excess of $E_{B-V}=0.26^m$, and a mean distance modulus of $V_0-M_v=12.29^m\pm0.12^m$ (s.e. mean for 11 stars), fully consistent with Turner (1982), whose results are based mainly on UBV photometry and fitting to the slightly evolved main sequences of NGC 3293. This independent determination confirms Turner's result, especially with respect to the absolute magnitude and probable membership of the pseudo-Cepheid V810 Cen. (14 refs.)

111162 Photoelectric photometry of globular clusters in the Andromeda Nebula. IX. A.S.Sharov, V.M.Lyuty, V.F.Esipov.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.393-4 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
For pt.VIII see ibid., vol.8, no.8, p.451-3 (1982). Results of photoelectric UBV photometry of 14 globular clusters in the Andromeda Nebula obtained in 1982 at the 2.6-m telescope are presented. (16 refs.)

98.40 INTERSTELLAR MATTER; AND NEBULAE

111163 The extraordinary extragalactic supernova remnant in NGC 4449. II. X-ray and optical investigations. W.P.Blair, R.P.Kirshner (Dept. of Astron., Univ. of Michigan, Ann Arbor, MI, USA), P.F.Winkler,Jr..
Astrophys. J. (USA), vol.272, no.1, pt.1, p.84-91 (1 Sept. 1983).
For pt.I see ibid., vol.236, no.1, p.135-42 (1980). X-ray observations with the Einstein Observatory show that the supernova remnant (SNR) in the galaxy NGC 4449 is the most luminous known X-ray SNR—a distinction it already holds at optical and radio wavelengths. New optical spectroscopy and the X-ray data indicate that the extraordinary luminosity is due to chemically enriched material at unusually high densities. A model in which the NGC 4449 remnant resulted from the explosion of a massive star in a medium of density near 25 cm^{-3} about 100 years ago is consistent with all of the data. Models in which chemically processed material makes up less of the X-ray emitting plasma are also possible. The detection of optical emission lines from [O II], [S II], and [Ne III] provides a refined picture of the physical conditions where the optical emission takes place and permits comparison of this remnant with others. The chemistry supports the picture that the remnant in NGC 4449 resulted from the explosion of a star of mass greater than 25 $M_\odot$. (44 refs.)

111164 Magnetic field structure in the Gum Nebula area. J.P.Vallee (Section d'Astron., Inst. Herzberg d'Astrophys., Nat. Res. Council of Canada, Ottawa, Ontario, Canada), R.C.Bignell.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.131-6 (1 Sept. 1983).
New rotation measure data are calculated from recent linear polarization observations for extragalactic radio sources in the direction of the Gum Nebula area. An analysis of these rotation measures, in conjunction with a model of the Gum Nebula or with a tangential view to an arm, sheds more light on the magnetic field distribution in the region. The observations are consistent with a shell model of the Gum Nebula whose magnetic field in the shell is about 2×10^{-6} gauss. This 'magnetic bubble' is the third to be found near the Sun. (13 refs.)

111165 Near-infrared spectrophotometry of planetary nebulae. P.D.LeVan (Air Force Geophys. Lab., Univ. of California, San Diego, CA, USA), R.J.Rudy.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.137-48 (1 Sept. 1983).
The results of an infrared spectrophotometric study of 10 planetary nebulae in the wavelength region from 0.85 to 1.4 μm are reported. Line strengths were measured for the Paschen lines Paβ and Paγ, the [S III] lines λ9069 and λ9532, and He I λ10830. Excess continuum flux found at 1.28 μm for five planetary nebulae is shown to be of central star origin. A discrepancy is found between the measured ratio of the λ10830 and λ5876 helium triplet line fluxes and previously predicted values. (43 refs.)

111166 The detection of vinyl cyanide in TMC-1. H.E.Matthews, T.J.Sears (Herzberg Inst. of Astrophys., Nat. Res. Council of Canada, Ottawa, Ontario, Canada).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.149-53 (1 Sept. 1983).
Observations of four rotational transitions of vinyl cyanide (CH_2CHCN) at λ3 cm and λ1.5 cm are reported. The molecule has been detected in the dense dark cloud TMC-1 for the first time and the observed relative intensities of the hyperfine components are consistent with those expected under LTE conditions. The CH_2CHCN column density in TMC-1 is 3×10^{12} cm^{-2}. Upper limits are reported for a number of other sources. (17 refs.)

111167 Radio images of the bipolar H II region S106. J.Bally (Bell Labs., Holmdel, NJ, USA), R.L.Snell, R.Predmore.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.154-62 (1 Sept. 1983).
Reports evidence for the presence of a circumstellar disk surrounding the exciting star of the bipolar H II region S106. Gas lying in the geometric shadow of this disk is shielded from direct ultraviolet illumination by the exciting star of the H II region. The high density of gas and dust within the disk may be responsible for the longevity of the disk against photoionization and ablation by the diffuse radiation from the H II region. The optically obscured exciting star of the He II region, S106 IR, lies at the center of the shadowed area. The radio and IR properties of this object indicate that it is probably a BO star possessing a massive stellar wind. The ionized gas distribution in the H II region is discussed. (36 refs.)

111168 Neutral interstellar gas in the lower galactic halo. C.E.Albert (Yerkes Obs., Univ. of Chicago, Chicago, IL, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.509-39 (15 Sept. 1983).
Optical interstellar absorption lines of Ti II, Ca II, and Na I, and the 21 cm emission line of H I have been observed at high resolution and high detection sensitivity toward nine pairs of nearly aligned distant halo stars and foreground disk stars with well-determined distances. Analysis of the column densities, velocities, and the directly determined variation of the titanium abundances with *z*-distance leads to a general picture of the neutral interstellar material in the lower galactic halo. Two types of gas with distant distribution, kinematics, and abundances are found: a thick, low-velocity disk (type A) extending from the plane to well beyond the thin disk of OB stars, and a high-velocity, much less strongly depleted gas (type B) observed only at *z*-distances, which constitutes at least 24% of the mass of the halo gas. The possible origins of the observed gas and its connection with QSO absorption lines are discussed. (104 refs.)

111169 Interpretation of neutral hydrogen spin temperature measurements. H.E.Payne (Nat. Radio Astron. Obs., Greenbank, WV, USA), E.E.Salpeter, Y.Terzian.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.540-50 (15 Sept. 1983).
Sensitive neutral hydrogen emission-absorption observations, which had used the 3′ Arecibo beam, are analyzed. Spin temperature results in the direction of 'small' and 'large' extragalactic sources are found to be statistically similar, showing that variations in derived spin temperature from case to case are real and not an artifact of the 'subcloudlet model'. The mean emission temperature as a function of velocity is found for widely dispersed warm material (INSA), which is independent of a cloud and is not strongly absorbing. Correcting the emission-absorption data for the contribution of the INSA emission gives cloud spin temperatures which vary roughly as the minus one-third power of the cloud optical depth. The data can be fitted by a composite model with cloud cores at gas kinetic temperatures of about 55K, but varying optical depths, surrounded by a warm (nonabsorbing) halo which contributes about 4.5K emission brightness. The analysis of cloud statistics by Crovisier (1981) is repeated, using more sensitive data. (35 refs.)

111170 Interstellar polarization, grain growth, and alignment. P.A.Aannestad (Dept. of Phys., Arizona State Univ., Tempe, AZ, USA), J.M.Greenberg.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.551-62 (15 Sept. 1983).
Shows that the observed correlation of the width of the normalized linear polarization curve with the wavelength of maximum polarization is most likely caused by the accretion of mantles on grains with an initial power-law size distribution. Calculations assuming Purcell's (1979) suprathermal alignment mechanism with the 'rocket' lifetime determined by a monolayer accretion time scale are discussed. The Davis-Greenstein (1951) thermal alignment mechanism cannot account for the observed correlation at large values of λ_{max}. The authors investigate the effect of subsonic turbulent coagulation on a power-law size distribution of grains. The predicted correlation between width and λ_{max} is at variance with the observed data. (45 refs.)

111171 A far-ultraviolet extinction law: what does it mean?. J.M.Greenberg, G.Chlewicki (Lab. Astrophys., Univ. of Leiden, Leiden, Netherlands).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.563-78 (15 Sept. 1983).
The dust grains in the diffuse cloud medium are characterized by a far-ultraviolet (FUV) extinction 'law' so that all curves have the same functional form for inverse wavelengths $\lambda^{-1}\gtrsim6$ μm^{-1}. A direction theoretical consequence of this fact that there is very little scattering by either the particles responsible for the FUV extinction or the 220 Å hump. A strong correlation between the strength of the 2200 Å hump and the visual extinction is confirmed. Poor correlation is found between the FUV extinction and either the 2200 Å hump or the visual extinction. All indications are that the dust grains responsible for the visual, the 2200 Å hump, and the FUV extinction are a trimodal distribution of independent groups of particles of which the latter two are rather strictly limited in radii (if treated as spheres) to $a\lesssim0.01$ μm. It is also that no Mie theory calculations using currently accepted graphite or silicate optical properties can provide the observed shapes of the ultraviolet and FUV extinction. (46 refs.)

111172 Synthesis of chain molecules in regions with partially ionised carbon. H.Suzuki (Dept. of Phys., Kyoto Univ., Kyoto, Japan).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.579-90 (15 Sept. 1983).
A chemical mechanism for the formation of carbon chain molecules is proposed, and its efficiency under interstellar conditions is investigated. In this chemical scheme, C^+ reactions have the essential role of chain growing. As high C^+ abundance and low photodissociation rates of hydrocarbons and chains are preferable, this mechanism is most effective in regions with partially ionized carbon. Since the reaction rates of radiative association generally become greater as the number of atoms in the reaction increases, the chain growing from C_3 chain to C_4 chain is the rate-determining reaction. Higher density, lower temperature, and lower intensity of the external radiation field provide favorable conditions for chain growing. Rapid condensation of cloud matter also favors chain growing because more carbon remains without changing to CO molecules. (56 refs.)

111173 The kinetic temperature and CH_3CCH column density profiles in Sgr B2, Orion, and DR 21. E.Churchwell (Univ. of Wisconsin-Madison, Madison, WI, USA), J.M.Hollis.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.591-608 (15 Sept. 1983).
Describes a simple technique for estimating kinetic temperatures from intensities of adjacent rotational transitions of symmetric top molecules. The method relies on two assumptions: (1) that the metastable levels (lowest energy level in each K ladder) are thermalized; and (2) that the excitation temperature connecting the upper level of the observed transition to the lowest level in the K ladder is the same for both adjacent transitions. The method is applied to observations of the $J=5$-4 and $J=6$-5 transitions of CH_3CCH obtained at 1′ intervals along a NS-EW cross centered on Orion KL, Sgr B2, and DR 21. (55 refs.)

111174 A large molecular cloud toward the SNR W50 and SS 433. Y.-L.Huang, T.M.Dame, P.Thaddeus (Columbia Univ., New York, NY, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.609-14 (15 Sept. 1983).
The CO $1 \rightarrow 0$ transition at 115 GHz has been mapped over an area of more than 6 deg^2 toward W50, the extended SNR surrounding the peculiar object SS 433. W50 is found to lie at the end of a filamentary molecular cloud 4° long and 1° wide that closely matches a conspicuous dust lane on the Palomar Sky Survey; the cloud's kinematic distance is 2.2 ± 0.7 kpc, in agreement with the distance 2-3.3 kpc estimated for the SNR, and its mass is about $1.2 \times 10^5\ M_\odot$. (31 refs.)

111175 Herbig-Haro objects in the dust globule ESO 210-6A. J.A.Graham, J.H.Elias (Cerro Tololo Inter-American Obs., La Serena, Chile).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.615-26 (15 Sept. 1983).
New narrow-band Hα and [S II] images of the dark globule ESO 210-6A and its associated Herbig-Haro objects HH 46 and HH 47 show additional emission knots. The HH objects are tightly collimated about an axis at PA 57°. New radial velocity measurements are presented. The HH objects appear to be a manifestation of bipolar outflow from an isolated star embedded in the globule. (27 refs.)

111176 Stability of the equilibrium distributions of interstellar gas, cosmic rays, and magnetic field in an external gravitational field. V.D.Kuznetsov, V.S.Ptuskin (Inst. of Earth Magnetism, Ionosphere & Propagation of Radio Waves, Acad. of Sci., Moscow, USSR).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.5-21 (July 1983).
An interstellar medium consisting of regular and turbulent magnetic fields, thermal gas and cosmic rays is tested for stability in a stellar gravitational field. Cosmic rays are described by the diffusion-convection equation and the stability region of the system is determined. It is shown that the presence of cosmic rays is a stabilizing factor if the cosmic-ray diffusion coefficient is sufficiently small. The dependence of the maximum growth rate of instability on the cosmic-ray diffusion coefficient is qualitatively determined. (22 refs.)

111177 The heterogeneous condensation of interstellar ice grains. J.Seki, H.Hasegawa (Dept. of Phys., Kyoto Univ., Kyoto, Japan).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.177-89 (July 1983).
Processes of heterogeneous condensation are investigated. The authors consider the situation that vapor and solid grains of which material is other than that of the vapor coexist and the saturation of the vapor increases with time. If the contact angle of the condensate to the solid is small ($\gtrsim 90°$), the condensate will be formed as mantles coating the solid grains but only a fraction of the solid grains will be coated by mantles. The ratio of core-mantle grains to bare solid grains in number will be smaller as the density of the vapor and the time scale of saturation increase are large. Actual calculations are made by adopting H_2O ice as the mantle material and magnesium silicate as the core material. (17 refs.)

111178 Interstellar proteins and the discovery of a new absorption feature at $\lambda=2800$ Å. L.M.Karim, F.Hoyle, N.C.Wickramasinghe (Dept. of Appl. Maths. & Astron., Univ. Coll., Cardiff, Wales).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.223-9 (July 1983).
The discovery of a broad interstellar absorption feature centred on 2800 Å in the extinction curve of starlight confirms the presence of proteinaceous material in grains. (9 refs.)

111179 Planck mean radiation-pressure cross sections for nonspherical grains. I. N.V.Voshchinnikov, V.B.Il'in (Leningrad State Univ., Leningrad, USSR).
Astrophysics (USA), vol.18, no.4, p.353-60 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.616-28 (Oct.-Dec. 1982).
Expressions are obtained for the efficiency factors for radiation pressure for infinite circular cylinders. The Planck mean radiation-pressure cross sections are calculated for statically oriented cylindrical grains composed of graphite, pure and contaminated iron, lead, silicates (obsidian and basalt), and silicon carbide. Particles with radii from 0.001 to 1 μm and the four effective temperatures 3300, 5770, 15500, and 40000K are considered. The dependence of the Planck mean cross sections on the temperature, grain diameter, and the direction of the incident radiation is discussed. (32 refs.)

111180 Interstellar C_2 in the Ophiuchus clouds. A.C.Danks (European Southern Obs., Santiago, Chile), D.L.Lambert.
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.188-96 (Aug. 1983).
Interstellar lines of the C_2 molecule are reported from high resolution high signal to noise spectra of ζOph, χOph and ρOph A. Rotational level populations for the C_2 toward ζOph are not described by a single rotational temperature. The populations are quite consistent with a competition between collisional and radiative excitation under conditions expected for the ζOph cloud. The excitation of the C_2 molecules toward χOph and ρOph A is similar to the results found for ζOph. The C_2 column density is $N(C_2)=2.2 \times 10^{13}$, 3.5×10^{13} and 2.6×10^{13} cm^{-2} toward ζOph, χOph and ρOph A respectively. (46 refs.)

111181 Spectrophotometry of low excitation Herbig-Haro objects. K.H.Bohm (Astron. Dept., Univ. of Washington, Seattle, WA, USA), E.W.Brugel, E.Olmsted.
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.23-8 (Aug. 1983).
New spectrophotometric observations of the low excitation Herbig-Haro object H-H7, H-H11, and H-H43 have been obtained with the Palomar 5.08 m telescope and the multichannel spectrometer. The results confirm that these objects show an unusually low degree of ionization indicating shock velocities of ~40 km s^{-1} or less. In spite of considerable differences between the line spectra of these low excitation and normal 'high excitation' H-H objects the low excitation objects show about the same continuum energy distribution as high excitation objects. The rapid rise of F_λ towards shorter wavelengths can (as far as we can see now) be attributed only to either a very hot black body or, more probably, to a two-photon continuum. (31 refs.)

111182 3-D simulations of the collapse of nonspherical interstellar clouds. M.Rozyczka (Inst. fur Astrophys., Max-Planck-Inst. fur Phys. und Astrophys., Garching, Munchen, Germany).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.45-51 (Aug. 1983).
A few numerical examples of the collapse of nonspherical interstellar clouds with initial density perturbations are presented. The calculations reach far into the non-linear regime and show that the growth rate of the perturbation as well as the probability of fragmentation are complicated functions of the initial conditions. It is found, in accordance with previously published results, that only high-amplitude or long-wavelength perturbations can evolve into well-defined fragments, which can survive the overall collapse of the cloud. The formation of spinning blobs is observed in the case of very strong initial density contrasts. (20 refs.)

111183 H_2 densities and masses of the molecular clouds close to the galactic center. R.Gusten, C.Henkel (Max-Planck-Inst. fur Radioastron., Bonn, Germany).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.136-45 (Aug. 1983).
Reports a high resolution study of the $H_2CO(2_{11}\text{-}2_{12})$ absorption line toward molecular clouds near the galactic center. A large-velocity gradient model of the 14.5 and 4.8 GHz H_2CO line excitation yields H_2 densities, abundances, and H_2 column densities. The high-density cores have masses of $10^6\text{-}10^7\ M_\odot$, and are stable against tidal disruption in the gravitational field of the central bulge. Comparison of the H_2CO (140 GHz) and NH_3 emission, and the H_2CO (14.5 GHz) absorption maps confirms earlier conclusions that the '20 km s^{-1} cloud' (M $0.13-0.08$) is in front of the Sgr A continuum, while the '40 km s^{-1}' (M $0.02-0.07$) lies on the far side of the galactic center and is sandwiched between Sgr A West and the non-thermal Sgr A East ridge. Carbon isotope ratios are inferred. (32 refs.)

111184 A note on compressibility and energy cascade in turbulent molecular clouds. R.C.Fleck,Jr. (Embry-Riddle Aeronautical Univ., Daytona Beach, FL, USA).
Astrophys. J. Lett. Ed. (USA), vol.272, no.2, pt.1, p.L45-8 (15 Sept. 1983).
A phenomenological theory of energy cascade in a compressible, turbulent fluid is outlined. For stationary flow, the turbulent velocity v, associated region size l, and fluid density ρ scale as $v \sim (l/\rho)^{1/3}$. Thus, in the interstellar medium where typically $\rho l \sim$ constant, the effect of compressibility is to steepen the velocity-size correlation as compared with the Kolmogorov result $v \sim l^{1/3}$ for incompressible turbulence. A comparison is made with the observed v-l-ρ power-law correlations for molecular clouds. (15 refs.)

111185 X-ray emission from pre-main-sequence stars, molecular clouds, and star formation. J.Silk (Inst. d'Astrophys., Paris, France), C.Norman.
Astrophys. J. Lett. Ed. (USA), vol.272, no.2, pt.1, p.L49-53 (15 Sept. 1983).
The pre-main-sequence X-ray emitting stars observed in molecular clouds appear to provide the bulk of the ionization. Newly forming stars therefore control the coupling of the magnetic field to the cloud. Since this coupling itself is believed to be responsible for the rate of cloud collapse, the authors argue that there is a natural feedback mechanism, involving observed X-rays, which is capable of regulating molecular cloud evolution and the rate of star formation. (27 refs.)

111186 Masses of interstellar gas clouds. V.B.Bhatia (Dept. of Phys. & Astrophys., Univ. of Delhi, Delhi, India).
Can. J. Phys. (Canada), vol.61, no.9, p.1305-7 (Sept. 1983).
The equilibrium masses of the interstellar gas clouds have been calculated when the clouds are imbedded with magnetic fields. It is found that the masses of these clouds may be of the order of several thousand solar masses. These masses appear to be consistent with the generally accepted level of efficiency for the processes of star formation. (9 refs.)

111187 On the calculation of ion-molecule reaction rates in interstellar space and planetary atmospheres. D.Mathur (Tata Inst. of Fundamental Res., Bombay, India).
Indian J. Radio & Space Phys., vol.12, no.2, p.59-61 (April 1983).
Ghosh and Ghosh (1982) have suggested the use of a simple equation to calculate the rate constant for ion-molecule reactions. This study points out inadequacies in the suggested approach and draws attention to experimental rate constants which are orders of magnitude different from the values deduced from the proposed equation. (19 refs.)

111188 High-resolution study of the supernova remnant G330.2+1.0. J.L.Caswell, R.F.Haynes, D.K.Milne, K.J.Wellington (Div. of Radiophys., CSIRO, Epping, NSW, Australia).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.915-20 (Sept. 1983).
Observes the radio supernova remnant G330.2+1.0 with resolution better than 1 arcmin using both the Fleurs synthesis telescope and the Molonglo Observatory synthesis telescope. The overall appearance is suggestive of a shell structure delineated by eight blobs of high brightness approximately equi-spaced round the periphery. A similar number of high-brightness blobs are seen well within the outer boundary. The irregular brightness variations are strikingly different from those seen in other supernova remnants and seem likely to be the result of a thin shell interacting with the interstellar medium, there is an underlying gradient of surface brightness, with the side towards the galactic plane being more intense. (17 refs.)

111189 A new radio map of the AD 1006 supernova remnant, G327.6+14.6. J.L.Caswell, R.F.Haynes, D.K.Milne, K.J.Wellington (Div. of Radiophys., CSIRO, Epping, NSW, Australia).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.921-6 (Sept. 1983).
The radio remnant of the AD 1006 supernova has been mapped with resolution of ~1 arcmin using the Fleurs synthesis telescope at 1.4 GHz. The radio map and a recent X-ray map of similar resolution both show a bright ring of emission indicative of a shell structure. While the general appearance is remarkably similar, with both radio and X-ray emission strong in the same general portions of the ring, detailed comparisons show no precise correspondence of the brightest features. A major difference is that the X-ray emission is quite intense at the centre of the ring, where there is essentially no detectable radio emission. Optical observations conflict with the X-ray interpretation of a large ejected mass, high energy and no deceleration to date. (15 refs.)

111190 8-13 μm spectral observations of eight moderately extended planetary nebulae. P.F.Roche, D.K.Aitken, B.Whitmore (Dept. of Phys. & Astron., Univ. Coll. London, London, England).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.1017-24 (Sept. 1983).
Obtains 8-13 μm spectra of eight moderately extended planetary nebulae at a resolution of 0.24 μm using a 20-arcsec circular aperture. More compact planetaries which have been studied in this way generally show a strong continuum due to emission from dust, together with fine structure line emission. In contrast, these more extended objects have very weak continuum emission, and are dominated by fine structure line emission, especially by [S IV] which in several cases accounts for most of the broad-band 10 μm flux. There appears to be very little warm ($\gtrsim$150K) dust in some of these objects. (19 refs.)

111191 He 2-442—two emission objects under the same name. V.P.Arkhipova, V.F.Esipov, B.F.Yudin, A.M.Mechetin.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.349-52 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
By means of an IR image tube two stellar sources (He 2-442A and He 2-442B) have been found at the place of the diffuse visual image of the peculiar object He 2-442 (PK 61+2°1). They are NE-SW directed with an angular separation of ~6″. The spectra of both sources in the 4000-6800 Å region are similar to those of planetary nebulae of the 3-4 excitation class. The spectrum of He 2-442B differs from that of He 2-442A mainly in the presence of the He II λ4686 line. The intensity of this line corresponds to a source temperature of $\sim 10^5$K. (9 refs.)

111192 Quasi-resonance collisional pumping of H_2O masers. D.A.Varshalovich, W.K.Kegel, S.Chandra.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.395-400 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
A new pumping mechanism is proposed for the strong H_2O masers associated with star-forming regions. This mechanism is based on the two following phenomena: (i) superthermal excitation of H_2 molecules as a result of the relaxation time difference in the post-shock cooling, and (ii) the quasi-resonance transfer of the superthermal excitation from H_2 to H_2O in their collisions. The necessary conditions and efficiency of this pumping mechanism are estimated. (12 refs.)

111193 On the evolution of Hα/N II in supernova remnants. J.Bohigas (Inst. de Astron., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico).
Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.4, p.271-84 (March 1983).
The line ratio Hα/N II in supernova remnants has been observed to evolve as a function of the expansion velocity. This is explained by assuming that the abundance of nitrogen with respect to hydrogen in the mass ejected by the supernova explosion or, prior to it, by the presupernova star, is higher than the average ambient value. The line ratio will increase as the relative abundance of nitrogen evolves towards the normal cosmic value as a result of accretion of interstellar material by the shock wave. The behavior of Hα/N II as a function of the radius of the supernova remnant and as a function of the [S II] line ratio 6717/6731 Å can also be explained with this model. (75 refs.)

111194 Faint early-type stars in the neighbourhood of the H II region RCW 99. M.Rabolli (Observatorio Astron., Univ. Nacional de La Plata, La Plata, Argentina).
Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.4, p.309-11 (March 1983).
Uses *UBV* photographic photometry to search for faint early-type stars in an area of about 600 square minutes of arc around the H II region RCW 99. The magnitude limits of the search are: $V=15.59$ mag, $B=16.70$ mag, and $U=17.49$ mag. Twenty seven new early-type stars were found. (46 refs.)

111195 High dispersion *IUE* observations of the planetary nebula NGC 3918. M.Pena, S.Torres-Peimbert (Inst. de Astron., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico).
Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.4, p.313-17 (March 1983).
Measures absolute fluxes of the lines present in a high dispersion short wavelength exposure of NGC 3918. Amongst the measured lines are several density dependent multiplets and the C IV and N V resonance doublets. The mean electron density derived is in agreement with previous determination. The authors find an anomalous value for the ratio of the 1239/1243 Å lines of NV and discuss its implications. (20 refs.)

111196 Bipolar nebulae and type I planetary nebulae. N.Calvet (Centro de Investigacion de Astron., Merida, Venezuela), M.Peimbert.
Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.4, p.319-28 (March 1983).
It is suggested that the bipolar nature of PN of Type I can be explained in terms of their relatively massive progenitors ($M_i \geq 2.4\ M_\odot$), that had to lose an appreciable fraction of their mass and angular momentum during their planetary nebula stage. The following objects are discussed in relation to this suggestion: NGC 6302, NGC 2346, NGC 2440, CRL 618, Mz 3 and M2-9. It is found that CRL 618 is overabundant in N/O by a factor of 5-10 relative to the orion Nebula. (58 refs.)

111197 Bipolar gas jets in star-forming regions. J.Bally (Bell Labs., Holmdel, NJ, USA).
Sky & Telesc. (USA), vol.66, no.2, p.94-7 (Aug. 1983).
Discusses the structure of bipolar nebulae. Gas velocities and distributions are considered in relation to the forming star. The relation between bipolar jets and nebulae is discussed. (no refs.)

98.50 THE GALAXY, EXTRAGALACTIC OBJECTS AND SYSTEMS

111198 The optical variability and spectrum of PKS 2155−304. H.R.Miller, H.A.McAlister (Dept. of Phys. & Astron., Georgia State Univ., Atlanta, GA, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.26-8 (1 Sept. 1983).
Photometry of the BL Lacertae object PKS 2155−304 has demonstrated that small-amplitude color variations accompany long-term trends in the optical variations of this object. These variations are similar to those found for the optically violent variable quasar 3C 446. These variations have been compared and found to agree well with a model suggested by Marscher (1980). Spectroscopy of PKS 2155−304 has failed to confirm the identification of the [O III] features and the redshift reported by Charles, Thorstensen, and Bowyer (1979). (15 refs.)

111199 The rate of star formation in normal disk galaxies. R.C.Kennicutt,Jr. (Dept. of Astron., Univ. of Minnesota, Minneapolis, MN, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.54-67 (1 Sept. 1983).
Photometry of the integrated Hα emission in a large sample of field spiral and irregular galaxies is used to obtain quantitative estimates of the total star formation rate (SFR) in the galaxies. The photoionization properties of a stellar population are modeled for a variety of choices for the initial mass function (IMF). The observed *UBV* colors and Hα emission equivalent widths place tight constraints on the slope of the IMF between 1 $M_\odot$ and 50 $M_\odot$ in the galaxies. The properties of late-type galaxies are not well reproduced by the Miller-Scalo solar neighborhood IMF. The extinction-corrected star formation rates are large, as high as 20 $M_\odot\ yr^{-1}$ in giant Sc galaxies ($H_0=50\ km\ s^{-1}\ Mpc^{-1}$). The current rates in late-type galaxies are comparable to the past rates averaged over the age of the disk; late-type disk galaxies have evolved at a nearly constant rate, confirming earlier models by Searle, Sargent, and Bagnuolo (1973). Little evidence is found for a strong correlation between the SFR and average gas density. Comparison of the present SFRs with the remaining supply of interstellar gas yields consumption time scales. These are discussed. Infall of intergalactic gas may extend these time scales. It is possible that the present epoch is characterized by rapid changes in the integrated properties and morphologies of disk galaxies. (58 refs.)

111200 The space density and spectroscopic properties of a new sample of emission-line galaxies. A.J.Wasilewski (Warner & Swasey Obs., Case Western Reserve Univ., Cleveland, OH, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.68-83 (1 Sept. 1983).
A moderate-dispersion objective prism survey for low-redshift emission-line galaxies has been carried out in an 825 sq. deg. region of sky. A 4° prism (400 Å mm^{-1} at Hβ) was used with the IIIa-J emulsion to show that a new sample of emission-line galaxies is available even in areas already well searched with the 'excess UV-continuum' technique. Spectroscopic observations with a fiber-controlled SIT spectrometer and the objective prism spectra yielded redshifts for two-thirds of the new emission-line galaxies. These galaxies occur quite commonly in systems with peculiar morphology indicating gravitational interaction with a close companion or other disturbance. About 10%-15% of the sample are Seyfert galaxies. An additional 20% exhibit the characteristics of starburst galaxies. It is suggested that tidal interaction involving matter infall may play a significant role in the generation of an emission-line spectrum. The space density of the new galaxies is investigated. (68 refs.)

111201 An infrared and optical investigation of galactic nuclei with compact radio sources. T.M.Heckman (Astron. Program, Univ. of Maryland, College Park, MD, USA), M.J.Lebofsky, G.H.Rieke, W.van Breugel.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.400-10 (15 Sept. 1983).
Presents infrared multicolor (JHKLN) photometry and optical spectrophotometry of a sample of bright ($m_v \leq 18$) galaxies with powerful compact nuclear radio sources ($S \geq 200$ mJy at 5 GHz). Nearly all of the objects (≥85%) have a nonstellar optical-infrared nuclear continuum whose strength is roughly proportional to that of the compact radio source. Except for their lower luminosities, the nuclei in these galaxies probably resemble radio-loud quasars. Compact nuclear radio sources with associated large-scale double radio lobes probably have enhanced nonstellar optical-infrared continua compared to the objects without such extended radio emission. The sample is diverse in its emission-line properties. Generally, the radio-loud objects have much stronger emission lines than do the nuclei of normal (radio-quiet) early-type galaxies. (45 refs.)

111202 X-ray, optical, and radio observations of the blue galaxy Butcher-Oemler 6 in the 3C 295 cluster. J.P.Henry (Inst. for Astron., Univ. of Hawaii, Honolulu, HI, USA), J.T.Clarke, S.Bowyer, R.J.Lavery.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.434-8 (15 Sept. 1983).
Investigates the nature of the blue members of distant, condensed clusters of galaxies through X-ray, optical, and radio observations of the brightest such object in the 3C 295 cluster. The X-ray luminosity and the optical emission line spectrum show that this galaxy is a Seyfert, in contrast to the original suggestion that the blue galaxies are rapidly evolving spirals. The observations yield an X-ray luminosity, strong optical emission lines of Mg II and [O II] at a redshift of 0.473, and an upper limit to the radio luminosity at 20 cm. Compared to other Seyfert galaxies, this object appears relatively X-ray luminous, shows an average Mg II/X-ray flux ratio, and is relatively weak in Hβ emission. (17 refs.)

111203 Globular cluster systems in the Hydra I elliptical galaxies. II. W.E.Harris (Dept. of Phys., McMaster Univ., Hamilton, Ontario, Canada), M.G.Smith, E.S.Myra.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.456-72 (15 Sept. 1983).
For pt.I see ibid., vol.205, p.709-15 (1976). Presents a deep ($B_{\rm lim}\approx 24.5$) photometric survey around NGC 3311, the giant central galaxy of the Hydra I (A1060) Cluster, to investigate the characteristics of its globular cluster system. Measurements of the images in a 7.4′ square field centered on NGC 3309/3311, compared with a 'background' field ~15′ away, used to derive various results. NGC 3311 is surrounded by an extensive and extremely populous cluster system. The NGC 3311 globular clusters appear in detectable numbers for $B_J>22$, increasing steadily to the survey limit. Their distribution in apparent magnitude is satisfactorily matched by the standard Virgo/Local Group luminosity function for globular clusters if Hydra is placed (2.0 ± 1.0) mag farther away than Virgo, NGC 311 represents the first additional example of a 'supergiant' or anomalously populous, globular cluster system, similar to the system in the Virgo giant elliptical galaxy M87. The authors discuss the possible connections between the M87 and NGC 3311 situations, with the tentative suggestion that their exceptional cluster populations may have been acquired at birth rather than in subsequent evolution. (32 refs.)

111204 Multicolor surface photometry of Markarian Seyfert galaxies. H.K.C.Yee (Steward Obs., Univ. of Arizona, Tuscon, AZ, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.473-83 (15 Sept. 1983).
Surface photometry of 20 Markarian Seyfert galaxies in three colors: r (6500 Å); g (4950 Å) and ν (3980 Å), obtained by using a SIT-vidicon camera, is used to study the host galaxies and nuclear components of Seyfert galaxies. From the profiles, it is found that the parameters of the disk components are similar to normal spiral galaxies, but with somewhat brighter central surface brightness. However, the discrepancies in the disk parameters can be attributed to selection effects and the problems in separating the nucleus from the galaxy. The color of the underlying galaxies are found to be comparable to those of normal spirals in the range from Sa to Sbc. Luminosities of the nuclear and galaxy components are estimated. (26 refs.)

111205 VLA observations of extragalactic NH_3 in IC 342. P.T.P.Ho (Radio Astron. Lab., Univ. of California, Berkeley, CA, USA), R.N.Martin.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.484-7 (15 Sept. 1983).
Aperture synthesis maps of the nuclear region in the nearby spiral IC 342 were made in the $(J,K)=(1,1)$ and (2,2) inversion lines of NH_3. NH_3 emission was not detected with an upper limit to the apparent brightness temperature of 0.5K (referred to 6″ resolution). Comparison with single-dish measurements indicates that the NH_3 emission in the nucleus of IC 342 must be distributed on a size scale greater than 130 pc. The authors interpret these results as favoring a model where the NH_3 emission is moderately optically thick, thermalized to a gas temperature of ~50K, and clumpy. This is consistent with a high OB star-formation rate in the nucleus accompanied by heated dust and gas. (10 refs.)

111206 The X-ray spectra of the BL Lacertae objects PKS 0548−322 and 3C 66A. D.Maccagni (CNR, Istituto di Fisica Cosmica, Milano, Italy), T.Maccacaro, M.Tarenghi.
Astrophys. J. (USA), vol.273, no.1, pt.1, p.70-4 (1 Oct. 1983).
Observes two BL Lac objects, PKS 0548−322 and 3C 66A with the Einstein Observatory. The authors combine the simultaneous imaging proportional counter and monitor proportional counter data to derive the energy spectra of the two sources between 0.2 and 10 keV. 3C 66A is found to be variable, both in intensity and spectra shape, within the data set. PKS 0548−322, which shows a constant behavior in the data, is inferred to have experienced a variation in its spectrum by comparison with results from other experiments. The authors discuss the implications of flux and spectral variability in BL Lac objects for models of X-ray emission mechanisms. (22 refs.)

111207 X-ray and UV observations of the BL Lacertae object 3C 66A. D.Maccagni, L.Maraschi, E.G.Tanzi (Istituto di Fisica Cosmica, CNR, Milano, Italy), M.Tarenghi, L.Chiappetti.
Astrophys. J. (USA), vol.273, no.1, pt.1, p.75-80 (1 Oct. 1983).
The energy distribution of the BL Lac object 3C 66A is investigated in the soft X-ray range by means of repeated observations with the Einstein Observatory and in the UV range by means of the IUE satellite. The available optical photometry from 1979 to 1981 is reported. 3C 66A is characterized by violet X-ray activity over a time scale of 6 months, probably uncorrelated with optical variations. The featureless UV continuum is steeper than that deduced from infrared broadband photometry, thus indicating a spectral break in the region 10^{14}-10^{15}Hz. The overall energy distribution is discussed in the framework of theoretical models proposed for BL Lac objects. (31 refs.)

111208 Spectrophotometry of 12 metal-poor galaxies: implications for the primordial helium abundance. D.Kunth (Inst. d'Astrophys., Paris, France), W.L.W.Sargent.
Astrophys. J. (USA), vol.273, no.1, pt.1, p.81-98 (1 Oct. 1983).
High-precision spectrophotometry is obtained for 12 emission-line galaxies, most of them dwarf systems. All except II Zw 40 have not been analyzed previously. Abundances were derived for He, N, O, and Ne relative to H. Particular attention was paid to the error analysis which takes into account errors in the raw fluxes, in the reddening correction, and in the electron temperature and electron density determinations. No correlation was found between the mass fraction of helium Y and the heavy-element abundances as represented by the O/H ratio. The authors therefore take the mean value of $Y_p=0.245\pm 0.003$ to be the best estimate of the primordial or pregalactic helium abundance and show that other estimates which lead to a lower value of Y_p do not stand up to critical study, usually because of lack of attention to errors. (44 refs.)

111209 Spectral evolution of galaxies. I. Early-type systems. G.Bruzuala (Centro de Investigaciones de Astron., Merida, Venezuela).
Astrophys. J. (USA), vol.273, no.1, pt.1, p.105-27 (1 Oct. 1983).
Develops models for the spectral evolution of early-type galaxies using population synthesis techniques. Different choices of the initial mass function and the star formation rate allow the construction of models which at the present epoch cover the range of observed galaxy spectra. Special emphasis is given to the ultraviolet region of the spectrum. Ultraviolet spectra of late-type stars and early-type galaxies obtained with the International Ultraviolet Explorer satellite are used. The evolving spectral energy distributions are used to compute galaxy colors, magnitudes, K-corrections, and evolutionary corrections as functions of redshift for different photometric systems. (80 refs.)

111210 The inner radio structure of Centaurus A: clues to the origin of the jet X-ray emission. J.O.Burns (Dept. of Phys. & Astron., Univ. of New Mexico, Albuquerque, NM, USA), E.D.Feigelson, E.J.Schreier.
Astrophys. J. (USA), vol.273, no.1, pt.1, p.128-53 (1 Oct. 1983).
Multifrequency (1.4 and 4.9 GHz) observations of the jet and inner lobes of the nearby radio galaxy Centaurus A (=NGC 5128) were made with all four configurations of the VLA. These data were used to construct maps of the total intensity and polarization at resolutions of 31″×10″ and 3.6″×1.1″. The results argue in favor of a common synchrotron radiation origin for the full spectrum jet emission. The implications of X-ray synchrotron radiation from $\gamma=8\times 10^7$ electrons on models of in situ particle acceleration are briefly considered. (68 refs.)

111211 The discovery of optical emission knots in the inner jet of Centaurus A. J.Brodie, A.Konigl, S.Bowyer (Astron. Dept., Univ. of California, Berkeley, CA, USA).
Astrophys. J. (USA), vol.273, no.1, pt.1, p.154-66 (1 Oct. 1983).
The authors have discovered three regions of intense optical emission in the inner ~2 kpc of the Cen A jet. Two of the regions coincide with X-ray and radio knots and emit strong optical continuum radiation with superposed emission lines. The third region, situated between the other two and coincident with a low surface brightness inter-knot zone in the radio and X-ray maps, has little continuum flux but still displays intense line emission which brightens up significantly at its downstream boundary. Spectra were obtained for each of the regions in the range 3700-7500 Å. The observed line emission is probably produced by shock heating or photoionization by a power-law continuum. The densities estimated in the continuum emission regions and in the inter-knot region are discussed. The authors attribute the line emission to dense clumps immersed in the flow and interpret the apparent flare-up at the edge of the inter-knot region in terms of a large-scale shock wave in the jet. The authors discuss the possible origins of the clumps and the shock. (47 refs.)

111212 MCG 5-29-86: a galaxy with a prolate central bulge?. K.-I.Wakamatsu (Junior Tech. Coll., Gifu Univ., Gifu, Japan), H.C.Arp.
Astrophys. J. (USA), vol.273, no.1, pt.1, p.167-76 (1 Oct. 1983).
MCG 5-29-86 is a 16th mag galaxy with a very peculiar appearance. Its main body looks like an inclined S0 galaxy with a pair of faint straight filaments along its minor axis. Optical spectra reveal no gaseous emission in the filaments of the galaxy. Radio observations with VLA reveal no radio material or central radio source. It is difficult therefore to interpret the filaments as jets due to internal activity. The authors discuss two other possible interpretations: (1) an edge-on galaxy with a polar ring; (2) an edge-on galaxy with a prolate bulge and a ring seen edge-on. No alternative is entirely satisfactory. Isophotometry of the object is discussed as it applies to these alternatives. (44 refs.)

111213 Photometric classification of normal galaxies and their redshift determination. V.Straizys, Z.Sviderskiene (Astron. Obs., Inst. of Phys., Lithuanian Acad. of Sci., Vilnius, Lithuanian SSR).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.23-30 (July 1983).
Two-color diagrams including magnitudes from several photometric systems are investigated with respect to the possibility of determining from the integrated photometry the galaxy type and its redshift. The color indices of galaxies are calculated using the energy distribution curves of Coleman et al. (1980). It is shown that redshift determination at low values of z requires an ultraviolet magnitude with λ_0 shorter than 300 nm. Different sources of errors and uncertainties are discussed. (26 refs.)

111214 Radial velocities of galaxies in neighborhoods of groups of galaxies. I. J.Vennik, A.Kaazik (Inst. of Astrophys. & Phys. of Atmosphere, Acad. of Sci., Estonian SSR).
Astrophysics (USA), vol.18, no.4, p.297-302 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.523-32 (Oct.-Dec. 1982).
New determinations of the radial velocities for 62 galaxies in the neighborhoods of groups of galaxies are presented. The rms error of the velocities is about 80 km/sec with the dispersion of the spectra 200 Å/mm. The possible membership of the observed galaxies to various types of systems is considered. (15 refs.)

111215 Radial velocities of galaxies in neighborhoods of groups of galaxies. II. J.Vennik, A.Kaazik, A.Amirkhanyan (Inst. of Astrophys. & Phys. of Atmosphere, Acad. of Sci., Estonian SSR).
Astrophysics (USA), vol.18, no.4, p.303-7 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.533-40 (Oct.-Dec. 1982).
For pt.I see Astrofizika, vol.18, no.4, p.523-32 (1982) or Astrophysics, vol.18, no.4, p.297-302 (1983). New determinations of the radial velocities of 48 galaxies that are predominantly situated in the neighborhoods of groups of galaxies are presented. (13 refs.)

111216 On Markaryan 6 and the problem of the intermediate Sy 1.5 type. E.E.Khachikyan, V.N.Popov, A.A.Egiazaryan (Byurakan Astrophys. Obs., USSR).
Astrophysics (USA), vol.18, no.4, p.308-12 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.541-7 (Oct.-Dec. 1982).
The results of new spectroscopic observations of the variable type 2 Seyfert galaxy Markaryan 6 are considered. It is shown that the short wave components of the hydrogen emission lines discovered in 1969 by Khachikyan and Weedman (1970, 1971) can still be observed in the spectrum of this galaxy. A decrease in the equivalent widths of both H_β and the forbidden lines N_1 and N_2 is noted. It is suggested that the so-called type Sy 1.5 galaxies are a short phase in the evolution of Sy 2 galaxies. (16 refs.)

111217 On the connection between Seyfert galaxies and neighboring objects. A.R.Petrosyan (Byurakan Astrophys. Obs., USSR).
Astrophysics (USA), vol.18, no.4, p.312-21 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.548-62 (Oct.-Dec. 1982).
A sample of Seyfert galaxies containing 161 objects has been compiled. To consider the question of the connection between Seyfert galaxies and neighboring objects counts have been made of galaxies in circles of diameter 1.5 Mpc around fixed Seyfert galaxies. It is found that: the Seyfert galaxies participate in the clustering tendency of galaxies; the type 2 Seyfert galaxies reveal a stronger tendency to participate in clustering of galaxies than the type 1 objects; and the type 2 Seyfert galaxies occur more often in isolated pairs of galaxies than the type 1 objects. (30 refs.)

111218 The radio luminosity function of Seyfert galaxies. R.A.Kandalyan (Byurakan Astrophys. Obs., USSR).
Astrophysics (USA), vol.18, no.4, p.331-6 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.580-8 (Oct.-Dec. 1982).
The radio luminosity function ($F(\geq P)$) is constructed on the basis of the complete sample of Seyfert galaxies brighter than 14.2^m. Determination of the dependence of the mean radio luminosity ($\bar{P}_{1.4}$) and the radio luminosity function on the optical luminosity (L_p) of the galaxies leads to relations of the form $\bar{P}_{1.4}\sim L_p^{1.2\&0.3}$ and $F(\geq P)\sim L_p^{1.3\pm 0.5}$. It is assumed that the probability of a Sy 1 galaxy being a radio source with luminosity log $P_{1.4}\geq 23.0$ is greater than for a Sy 2 galaxy. (27 refs.)

111219 Numerical investigation of the generation of global spiral structure in interacting galaxies. V.I.Korchagin, Yu.G.Shevelev (Rostov-on-Don State Univ., Rostov, USSR).
Astrophysics (USA), vol.18, no.4, p.337-40 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.589-95 (Oct.-Dec. 1982).
A numerical investigation is made of the time-dependent nonlinear response generated in the flat gas subsystem by a satellite rotating in the plane of a galactic disk in the direction of its rotation. Besides the features typical of

interacting galaxies (bridge and satellite tail), there is excited in the disk an asymmetric spiral structure of 20-30% amplitude comparatively close to the center of the galaxy. This confirms the conclusion of Kormendy and Norman (1979) that satellites of interacting galaxies are one of the possible mechanisms of generation of global spiral patterns. (12 refs.)

111220 Collisions of massive gas clouds with primordial chemical composition. A.A.Suchkov, Yu.A.Shchekinov, M.A.Edel'man (Rostov State Univ., Rostov, USSR).
Astrophysics (USA), vol.18, no.4, p.360-7 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.629-40 (Oct.-Dec. 1982).
A study is made of the thermochemical evolution of matter with primordial chemical composition in collisions of gas clouds at velocities 40-200 km/sec; the masses of the clouds are $M=10^6\text{-}10^9 M_\odot$. The variations in time of the temperature, degree of ionization, and concentration of H_2 and HD molecules behind the shock front are found. It is shown that H_2 and HD molecules are formed in appreciable numbers; they ensure cooling of the gas to temperatures $T \sim 10\text{-}30$K. The results are discussed in connection with the problem of star formation in the early stages of galaxy formation. (16 refs.)

111221 The nature of the nebula around BL Lacertae. K.D.Rakos, N.Fiala (Inst. fur Astron., Univ. Wien, Wien, Austria).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.L11-12 (Aug. 1983).
New deep, high resolution images of the nebula around BL Lac are presented. These images indicate a spiral structure of the nebula surrounding BL Lac. The brightness distribution along a section through the proposed spiral arms is given. (9 refs.)

111222 Super-Eddington luminosity characteristics of active galactic nuclei. L.Bassani, A.J.Dean, S.Sembay (Phys. Dept., Southampton Univ., Southampton, England).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.52-8 (Aug. 1983).
Analysis of the variability timescale-bolometric luminosity relation for active galaxies, including Seyferts, quasars and BL Lac objects, shows that a number of sources violate the classical Eddington limit. A more realistic formulation of this limit which takes into account the effects of beaming and/or decreasing scattering cross section as evaluated from the Klein-Nishina relationship is discussed in the context of contemporary black hole accretion models. Most of the objects which satisfy this luminosity limit are therefore compatible with the existence of massive black holes at this nuclei. It is found, for the remaining objects, that the violation of this limit is removed if a closed Universe with a value of $H_0 \approx 100$ km s^{-1} Mpc^{-1} is assumed. (96 refs.)

111223 R136: supermassive star or dense core of a star cluster?. A.F.J.Moffat, W.Seggewiss (Obs. Hoher List, Univ.-Sternwarte Bonn, Daun, Germany).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.83-92 (Aug. 1983).
High signal-to-noise optical spectroscopy exhibits the type WN6+03-4 for the central $2.5'' \times 5''$ of R 136=HD 38268, the diffuse, luminous core object of the very young cluster NGC 2070 in the giant 30 Doradus nebula in the Large Magellanic Cloud. The published UV spectrum in the central 3″ diameter (Ø) can also be synthesized by the superposition of the spectrum of one or more WN stars with several O3 stars. The light distribution within R 136 and the surrounding cluster NGC 2070 from $Ø \approx 1.5''$ (~ seeing disk) to $Ø \approx 2'$ (maximum extent of the obvious cluster) is comparable to that seen in spherical stellar systems. The central projected surface brightness within $Ø \approx 0.50$ pc(2″) is not unusually intense. Published speckle interferometry reveals either a single central star (Meaburn et al., 1982) which cannot be brighter than $V \approx 12$ ($M_v \approx$-8) at the centre of R 136, or several (thus fainter) components (Weigelt, 1981). The latter is supported by the old astrometric observations of Innes (1927). An assessment of new differential photoelectric photometry and already published photometry suggests that R 136 is probably not variable. Marginally real radial velocity variations of the broad He II λ 4686 emission line show a possible 4d periodicity with low amplitude. If real, the best explanation is that the WN 6 component may be part of an unresolved spectroscopic binary. The best overall interpretation of R 136 is that it represents the dense stellar core of a populous cluster. (70 refs.)

111224 Periodic orbits in elliptical galaxies. E.Davoust (Obs. de Besancon, CNRS, Besancon, France).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.101-8 (Aug. 1983).
Using the analytical method of Lindstedt the author makes an inventory of the regular families of periodic orbits inside non rotating model elliptical galaxies of oblate and prolate shape, in particular at and near resonances. The author also obtains periodic solutions approximated by formal trigonometric series and a third integral of motion which, to first order, depends on the square of the total angular momentum. (33 refs.)

111225 Are galaxy properties specific for their parent clusters?. R.C.Kraan-Korteweg (Astron. Inst., Univ. Basel, Binningen, Switzerland).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.109-11 (Aug. 1983).
It is pointed out that the distance-independent relation between the 21 cm line width and the infrared surface brightness of spiral galaxies is different in different clusters. If this effect is not due to observational errors, it constitutes additional evidence for varying galaxian properties from cluster to cluster. (16 refs.)

111226 Quasi-simultaneous ultraviolet and optical observations of PKS 2155−304=H 2155−304. L.Maraschi, E.G.Tanzi (Istituto di Fisica Cosmica, CNR, Milan, Italy), M.Tarenghi, A.Treves.
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.117-20 (Aug. 1983).
The BL Lac object PKS 2155−304 was repeatedly observed in the 1200-3000 Å band with the International Ultraviolet Explorer. The variability of the source in this band is studied in detail. The UV continua are well fitted by power laws with frequency spectral index α_ν varying between −0.7 and −0.9. An optical spectrum was taken within one day from a UV spectrum. Combining the observations in the two ranges, evidence is found of a spectral steepening by $\Delta\alpha_\nu=0.36$ around 10^{15}Hz. (15 refs.)

111227 Magnitude-redshift relation in clusters, groups and pairs of galaxies. T.Jaakkola (Obs. & Astrophys. Lab., Univ. of Helsinki, Helsinki, Finland).
Astron. Nachr. (Germany), vol.304, no.3, p.103-23 (1983).
The magnitude-redshift relation within systems of galaxies is detailed in several kinds of systems. The main data contains 17 clusters, 64 groups, 121 pairs and 14 systems with two measured members, altogether 1043 galaxies in 162 separate systems. In addition, another sample of nearby groups and pairs, data on six clusters with 121 measured members, as well as 65 compact galaxies in four groups and 23 pairs are studied. Some properties of the velocity (redshift) dispersion are discussed. (57 refs.)

111228 High-resolution optical observations of NGC 3379. I. An analysis of previous data. J.-L.Nieto (Obs. du Pic-du-Midi et de Toulouse, Bagneres-de-Bigorre, France).
Astron. & Astrophys. Suppl. Ser. (France), vol.53, no.2, p.247-53 (Aug. 1983).
Analyses the photometric data on the galaxy NGC 3379 previously published in the literature, as a first step toward photometric studies of the central regions of galaxies at high resolution (FWHM ~0.5″-1.0″). The author suggests some corrections to the EW luminosity profile derived by de Vaucouleurs and Capaccioli (1979). The revised EW profile has a central surface brightness 0.15 mag $arcsec^{-2}$ brighter. Other data are transformed to EW profiles. The comparison of all the EW profiles is discussed. (11 refs.)

111229 Neutral hydrogen observations of double spiral galaxies. II. NGC 3958/3963, NGC 5289/5290, NGC 5673/IC 1029, NGC 5107/5112. G.A.van Moorsel (Kapteyn Astron. Inst., Univ. of Groningen, Groningen, Netherlands).
Astron. & Astrophys. Suppl. Ser. (France), vol.53, no.2, p.271-86 (Aug. 1983).
For pt.I see ibid., vol. 107, no.1, p.66-74 (1982). Full synthesis H I observations of four fields containing a binary galaxy system are presented. Individual total masses derived from the rotation curves are compared with the mass of the system as deduced from the observed orbital motion. The pairs NGC 3958/3963 and NGC 5673/IC 1029 show minimum orbital masses which are larger than the sum of the individual masses. The discrepancy is largest for the pair NGC 5673/IC 1029, which is likely part of a quadruple system. The other two pairs have minimum orbital masses smaller than the sum of the individual masses. Six of the eight galaxies show asymmetries in the H I distributions which are probably due to interaction with the other pair member. (18 refs.)

111230 Very large spiral galaxies. W.Romanishin (Astron. Dept., Univ. of California, Los Angeles, CA, USA).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.909-14 (Sept. 1983).
Observations of large spiral galaxies are potentially useful for cosmological tests and studies of galaxy evolution. As a first step in a systematic study of large spirals, a catalogue of the 107 largest known spiral galaxies is presented. These galaxies have isophotal diameters ($\mu_B=25.0$ mag $arcsec^{-2}$) greater than 90 kpc, assuming $H_0=50$ kms^{-1} Mpc^{-1}. New UBVR photoelectric photometry is presented for 20 of these galaxies. The absolute magnitudes of all galaxies in the catalogue are derived using Zwicky magnitudes transformed to the B_T system. (12 refs.)

111231 The structure of the Carina dwarf elliptical galaxy. S.Demers, S.Beland (Dept. of Phys. & Obs. Astron. du Mont Megantic, Univ. de Montreal, Montreal, Canada), W.E.Kunkel.
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.354-7 (June 1983).
The structure of the Carina dwarf elliptical galaxy is determined from counts of over 8000 stars on prints made from a CT10 4-m prime-focus blue plate. Carina has an ellipticity of $E=0.4$ to $r=11'$. Its tidal radius is 33′. If its luminosity function is similar to M3, its mass is 5.3×10^5 $\mathfrak{M}_\odot$. (11 refs.)

111232 Probable association of UX Piscium with a galaxy. A.R.Klemola (Lick Obs., Univ. of California, Santa Cruz, CA, USA).
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.368-9 (June 1983).
The poorly observed SRa-type variable star UX Psc appears to coincide with a sixteenth-magnitude galaxy. Although the limited observations given in this paper do not support the reported variability, further photometric observations are needed to clarify the nature of this object. (6 refs.)

111233 UV-continuum galaxies with double-nucleus structure: mass-to-luminosity ratio. A.R.Petrosyan.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.339-41 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
For 23 UV-continuum galaxies with double-nucleus structure, the radial velocity differences of their nuclei, their linear separations, luminosities and mass-to-luminosity ratios are presented. The mean mass-to-luminosity ratio for double-nucleus galaxies is equal to 3.8 ± 1.6, typical for galaxies with late-type morphology which have enhanced gas and young stellar contents. The result is in good agreement with $\mathfrak{M}/L$ for pairs of galaxies with Markarian components. (23 refs.)

111234 The dwarf irregular galaxy VV 574: a possible member of the M81 group. V.P.Arkhipova, R.I.Noskova.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.342-4 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Radial velocities in the galaxy VV 574—a possible nest of interacting galaxies—have been measured. No large internal motions are found. The rotation velocity does not exceed 10-15 km/s, giving a mass of $\approx 10^7$ $M_\odot$. The electron density derived from [SII] lines is 10^3 cm^{-3} and the ionized hydrogen mass is $\sim 10^4$ $M_\odot$. VV 574 appears to be a dwarf irregular galaxy with an absolute magnitude of $M_B=-11^m$ belonging to the M81 group. (5 refs.)

111235 Phenomena in the center of the Galaxy as a consequence of a recent supernova outburst. I.S.Shklovskii.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.345-8 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Argues that the whole complex of phenomena observed in the galactic center can be explained by a supernova outburst in a massive binary system which occurred ~100 years ago. The object should be similar to SS 433 except that it would be considerably younger and much more compact and active. The recently discovered anomalously-high helium abundance is explained by an expanding remnant of a massive helium star explosion. The 511 keV annihilation line emission is associated with the intense generation of electron-positron pairs in a neutron star magnetosphere. (13 refs.)

111236 Redshifts of blue galaxies in the direction of the Virgo cluster. I.D.Karachentsev, V.E.Karachentseva, F.Borngen.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.387-8 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Redshifts for 35 faint ($m=16\text{-}20^m$) blue galaxies from the Borngen's (1980, 1983) lists are presented. (4 refs.)

111237 Velocity field in the central region of Mark 617 galaxy. W.L.Afanas'ev, S.S.Rassokhin.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.389-92 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Using spectrograms obtained on the diffraction spectrograph with image tube in the primary focus of the 6-m telescope, the velocity field in the central region of Mark 617 galaxy is investigated. Noncircular motions of gas found in the narrow interval of position angles of 70°-90° are explained by gas ejection from the nucleus along the small axis of the galaxy. The possible existence of large-scale radial motions of gas is noted. (6 refs.)

111238 Dissipative capture of stars by the active objects in galactic nuclei. E.Ya.Vilkoviskii.
Pis'ma v Astron. Zh. (USSR), vol.9, no.7, p.405-8 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
It is shown that the gas mass in the environment of a massive object ($M \sim 10^8 M_\odot$) in an active galaxy nuclei leads to the intensive capture of stars by this object provided its radius $R \sim 100 Rg = 200\ GM/c^2$ and the mass of the gas $Mg_{as} \gtrsim 0.01\ M$. (13 refs.)

111239 The [N II]/[S II] galactic gradient derived from SNRs. J.Gonzalez (Inst. de Astron., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico).
Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.4, p.289-91 (March 1983).
From 17 SNRs that cover a galactocentric range $5 < R < 14$ kpc a gradient of -0.05 ± 0.01 dex kpc^{-1} is found in the [N II]/[S II] line intensity ratio. This value is very similar to that derived from H II regions and is probably related to a N/S abundance gradient. The possibility of contamination of the N/S ratio by SN as well as the variation of the [N II]/Hα ratio with galactocentric distance are also discussed. (32 refs.)

111240 Spiral structure and gas motion in M81. V.G.Berman, Yu.N.Mishurov (Rostov Univ., Rostov, USSR).
Sov. Astron. (USA), vol.26, no.6, p.639-42 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1055-61 (Nov.-Dec. 1982).
From the two-component spiral-structure model proposed by Marochnik, Mishurov, and Suchkov, the spiral-arm geometry in the galaxy M81 is calculated and the density-wave parameters are evaluated: the pattern speed $\Omega_p \approx 20$ km sec^{-1}kpc^{-1} and the effective rotating component has a surface density $\sigma_1 \approx 50\ M_\odot/\mathrm{pc}^2$. The nonlinear gas glow in the gravitational field of the arms is calculated for these parameters. Comparison with the observed radial distribution of H II regions, the radial-velocity profile of the gas along the minor axis, and the gas density profiles in the arms indicates that the spiral gravitational-force amplitude $F \approx 5\%$ at 8-kpc distance from the center of the system. (29 refs.)

111241 An evolutionary scheme for active-nucleus objects. B.V.Komberg (Inst. for Space Res., Acad. of Sci., Moscow, USSR).
Sov. Astron. (USA), vol.26, no.6, p.643-7 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1062-9 (Nov.-Dec. 1982).
The features typical of active nuclei in galaxies and the conditions necessary for activity are discussed. QSIs may represent nuclei of luminous galaxies in an early, particular violent evolutionary phase. The spectroscopic properties of the various species of quasar-like objects suggest a possible evolutionary sequence from those with Sy, O, I (Seyfert 1) spectra to Sy II, III spectra. An evolutionary scheme is outlined whereby the active nuclei in various types of galaxies would correspond to well-evolved QSOs belonging to either spheroidal [QSO(E)] or flat [QSO(S)] systems. These two kinds of QSOs may be either strong radio emitters [QSS(E), QSS(S)] or weak radio emitters [QSG(E), QSG(S)], a distinction which would manifest itself, in evolutionary terms, as the difference observed between the radio properties of radio galaxies and Seyferts, on the one hand, and normal E, S galaxies with low-activity nuclei, on the other. QSO(S)s should be scores of times as common in the Universe as QSO(E)s; there may be as many as 10^{-6} QSG(S) per Mpc^3. Such objects should contribute significantly to counts of blue 21^m-23^m starlike images. (54 refs.)

111242 Observations of galaxies of high surface brightness at 102 MHz. V.S.Artyukh, V.G.Malumyan, M.A.Ogannisyan (Lebedev Phys. Inst., Acad. of Sci., Moscow, USSR).
Sov. Astron. (USA), vol.26, no.6, p.650-3 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1075-80 (Nov.-Dec. 1982).
Forty-four of the galaxies of high surface brightness listed by Arakelyan have been observed at 102-MHz frequency with the Pushchino cophased antenna array by the interplanetary-scintillation method. Ten of these objects have been detected at flux-density levels above 1-2 Jy. Seven of them have scintillating components $\leq 1''$ across. The galaxy Ark 448 shows 100% scintillation; Ark 451, nearly 100%. Spectra are established for the scintillating components. Almost all the scintillators either are E or SO galaxies or appear highly compact at photographic wavelengths. (28 refs.)

111243 The stability of a differentially rotating disk of stars. S.V.Chalov (Inst. for Space Res., Acad. of Sci., Moscow, USSR).
Sov. Astron. (USA), vol.26, no.6, p.654-8 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1081-8 (Nov.-Dec. 1982).
The problem of whether certain models of infinitely thin, differentially rotating disks of stars will be stable against double-arm spiral disturbances is solved. Both the differential rotation and the spherical component of the galaxy will serve to stabilize the bar mode. (11 refs.)

111244 The distinction between Seyfert 1 and Seyfert 2 galaxies. A.S.Zentsova (Ioffe Phys. & Technol. Inst., Acad. of Sci., Leningrad, USSR).
Sov. Astron. (USA), vol.26, no.6, p.658-60 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1089-92 (Nov.-Dec. 1982).
The activity of the nuclei of Seyfert 1 galaxies could represent two-temperature disk-type accretion onto a supermassive black hole, while the activity in Seyfert 2 nuclei would correspond to the accretion regime of an optically thin disk. The parameters of such a disk are evaluated. Seyfert 2 nuclei should generate an X-ray luminosity $L_x = 10^{42}$-10^{43} erg/sec, the flux declining exponentially with energy for $h\nu \gtrsim 10$ keV. (16 refs.)

111245 Two-dimensional spectrophotometry of the cores of X-ray luminous clusters. L.L.Cowie (Dept. of Phys., MIT, Cambridge, MA, USA), E.M.Hu, E.B.Jenkins, D.G.York.
Astrophys. J. (USA), vol.272, no.1, pt.1, p.29-47 (1 Sept. 1983).
Describes the results of a two-dimensional spectrophotometric survey of the core regions of 11 rich clusters of galaxies. Fields of view of 4.5′ were observed with a CCD camera through 20 or 70 Å filters centered on wavelengths corresponding to redshifted Hα, [N II] 6583 Å, [S II] 6716, 6731 Å, [Fe X] 6374 Å, and various continuum bands. A number of these clusters have spectacular optical emission line systems in their cores. Both morphologically and kinematically the emission line regions divide into extended ~20-100 kpc systems of long linear filaments associated with the cluster core and more compact homogeneous elongated regions associated with the dominant central cluster galaxy. In some clusters both types of systems are seen, while in other clusters the extended filamentary structures or the emission from the central galaxy occur separately. The authors argue that the results are expected as hot X-ray emitting gas cools in the cluster center. The morphology of the systems can be understood if the filaments form initially in the cooling flow and, in some cases, are subsequently accreted by the central galaxy. (66 refs.)

111246 The X-ray emitting gas in poor clusters with central dominant galaxies. G.A.Kriss (Dept. of Phys., MIT, Cambridge, MA, USA), D.F.Cioffi, C.R.Canizares.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.439-48 (15 Sept. 1983).
X-ray observations of 16 poor clusters containing central dominant galaxies have been performed with the Imaging Proportional Counter of the Einstein Observatory. Twelve clusters were detected, and in each case the X-ray emission is centered on the dominant galaxy. The X-ray surface brightness implies density profiles that are roughly inversely proportional to radius. The low

temperatures and high central densities observed for the brightest clusters give central cooling times implying that radiative accretion flows may be present. The authors find total binding masses within 0.5 Mpc. The mean mass-to-light ratio for the bright clusters is ~70-100 $M_\odot/L_\odot$. Comparison of the deduced distribution of binding mass with the light distribution of the central galaxies of four clusters shows that M/L rises to over 200 $M_\odot/L_\odot$ in the galaxy halos. Thus these halos, like the clusters themselves, must possess dark matter. The X-ray data show clearly that the dominant galaxies sit at the bottoms of the poor cluster gravitational potential wells. This suggests a similar origin for dominant galaxies in poor and rich clusters. (52 refs.)

111247 Radiative accretion of intracluster gas onto dominant galaxies in poor clusters. C.R.Canizares, G.C.Stewart, A.C.Fabian (Inst. of Astron, Univ. of Cambridge, Cambridge, England).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.449-55 (15 Sept. 1983).
Finds that the hot gas in poor clusters is cooling and accreting onto the central, dominant galaxies. The evidence comes from the analysis of X-ray images of MKW 4, MKW 3s, AWM 4, and AWM 7 obtained with the Einstein Observatory and reported by Kriss, Cioffi, and Canizares (1983). Qualitatively, the presence of cooling and accretion can be deduced in a model-independent fashion from the sharply peaked central surface brightness distributions. Quantitatively, the authors apply the deprojection technique of Fabian et al. (1980, 1981) to deduce detailed density and temperature profiles for a wide range of assumed parameters. The authors compute mass accretion rates. The authors conclude that the high gas densities that give rise to cooling flows are not primarily the result of dynamical evolution of the cluster, in particular the merger of galaxies to form the dominant galaxy. Rather the general initial condition of high material density—both galaxies and gas—favors both mergers and cooling flows. (40 refs.)

111248 Filamentary galaxy clustering: a mapping algorithm. J.E.Moody (Dept. of Phys., Princeton Univ., Princeton, NJ, USA), E.L.Turner, J.R.Gott,III.
Astrophys. J. (USA), vol.273, no.1, pt.1, p.16-23 (1 Oct. 1983).
The Shane-Wirtanen galaxy count catalog gives the strong visual impression of large-scale linear or filamentary features in the galaxy distribution. Computer simulations of hierarchical galaxy clustering constructed to have two-, three-, and four-point autocorrelation functions like those observed do not have such an appearance. A simple and well-defined algorithm which maps and quantifies filamentary structure is developed. It appears to be successful in identifying those (and only those) filaments which the eye picks out in the Shane-Wirtanen catalog and thus provides an objective tool for studying these structures. A catalog and map of the most prominent Shane-Wirtanen filaments is given. Application of the algorithm to a computer simulation of hierarchical galaxy clustering is discussed. (21 refs.)

111249 Redshifts of groups and clusters in the rich superclusters 1451+22 and 1615+43. R.Ciardullo (Univ. of California, Los Angeles, CA, USA), H.Ford, F.Bartko, R.Harms.
Astrophys. J. (USA), vol.273, no.1, pt.1, p.24-35 (1 Oct. 1983).
Redshift measurements and finding charts are presented for galaxy clusters in the field of two rich, distant superclusters. Both systems are shown to have morphological and dynamical properties similar to the nearby superclusters, including small internal velocity dispersions and high density contrasts in redshift space. These data are consistent with two interpretations: either both superclusters are highly flattened systems with major axes close to the plane of the sky or the observed velocity dispersions do not arise from unperturbed Hubble flow. If the latter explanation is correct, these radial velocity data are a powerful probe of the large scale matter density in the Universe. (37 refs.)

111250 Virial mass and luminosity of the Virgo cluster of galaxies. I.D.Karachentsev (Special Astrophys. Obs., Acad. of Sci., USSR).
Astrophysics (USA), vol.18, no.4, p.279-85 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.501-11 (Oct.-Dec. 1982).
New measurements of the radial velocities and apparent magnitudes of the galaxies in the Virgo cluster made by Karachentsev and Karachentseva (1982) are used to determine the main dynamical parameters of the system. The dispersion of the radial velocities is plotted as a function of the radius r and the apparent magnitude m_B of the galaxies out to $r<6°$ from the center of the cluster. The luminosity function of the cluster is determined in the range $-22^m<M<-13^m$. The ratio of the virial mass to the luminosity of the Virgo cluster is $f=396\,f_\odot$. (26 refs.)

111251 The cluster of galaxies SC 0316−44. Does it rotate?. J.Materne, U.Hopp (Inst. fur Astron. & Astrophys., Tech. Univ. Berlin, Berlin, Germany).
Astron. & Astrophys. (Germany), vol.124, no.2, pt.1, p.L13-15 (Aug. 1983).
15 new radial velocities are presented in the region of the galaxy cluster SC 0316−44. The velocity distribution of the galaxies in this cluster appears to be asymmetric. The NE part seems to approach, the SE part to recede with respect to the cluster centre. It is proposed that this might be an indication of rotation. (16 refs.)

111252 Effect of cut-off inference on the redshift anomaly of galaxies in the Perseus supercluster. E.Giraud (Inst. Henri-Poincare, Paris, France).
C.R. Seances Acad. Sci. Ser. II (France), vol.296, no.21, p.1647-50 (13 June 1983). In French.
The magnitude cut-off inference on the redshift excess of the Sb, Sbc, Sc galaxies situated in the Perseus filament central cluster is studied. The excess does not vanish after a selective cut-off of the Sb, Sbc, Sc ($m_0\leq12.4$) and S0($m_0\leq13.4$) samples. (7 refs.)

111253 Where is the location of blue low-luminosity galaxies observed in the Virgo cluster?. A.V.Zasov.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.327-31 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Blue galaxies of low luminosity in the region of the Virgo cluster have an unusual radial velocities distribution, which differs from that of the normal galaxies in this cluster. It is argued that these galaxies are located in an extended expanding envelope (supercorona) of the cluster. (21 refs.)

111254 The distribution of centers of double galaxies. I.D.Karachentsev, A.L.Shcherbanovskii.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.332-8 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
For a complete sample of northern sky double galaxies with measured radial velocities the spatial distribution of their centers is considered. At different spatial scales mutual grouping of pairs is caused by their membership of systems of galaxies. The spatial two-point correlation function for the pair centers is constructed. Favourable conditions for double system formation may exist in the outlying regions of superclusters of galaxies. (14 refs.)

98.70D Discrete radio sources

111255 Statistical investigations of the physical properties of radio sources. B.Krygier (N. Copernicus Univ., Radio Astron. Obs., Torun, Poland), J.Krempec-Krygier.
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.145-57 (July 1983).
Six complete samples of radio sources are analysed by the Spearman rank and the Spearman partial-rank correlation coefficients. The relations between the radio luminosities and linear sizes as well as between linear sizes and redshift indicate that the observed angular diameter-redshift diagram may be explained by the changes of linear sizes with radio luminosity of radio sources. (36 refs.)

111256 The Cherenkov effect and plasma turbulent reactors. R.D.Lomadze (Abastumani Astrophys. Obs., USSR).
Astrophysics (USA), vol.18, no.4, p.367-73 (Oct.-Dec. 1982). Translation of: *Astrofizika (USSR)*, vol.18, no.4, p.641-50 (Oct.-Dec. 1982).
The restrictions on the energy interval of the power-law distribution function of the power-law distribution function of the relativistic electrons formed in a plasma turbulent reactor due to the Cherenkov effect and ionization losses are determined together with the signs of the curvature of the distortions of the distribution function at low energies. The possibility of interpreting features in the radiation spectra of cosmic radio sources in the decameter wavelength range is discussed. (14 refs.)

111257 The cluster around 3C 130. W.J.Jagers (Sterrewacht Leiden, Leiden, Netherlands).
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.172-4 (Aug. 1983).
Radio observations of the narrow edge-darkened double source 3C 130, with the 3 km Westerbork Telescope at 0.6 GHz are presented. Two additional narrow edge-darkened radio sources are visible in the same radio map. The author suggests that the three sources are members of the same large cluster with a diameter of at least 6 Mpc. (13 refs.)

98.70J Quasars

111258 Optical variability, absolute luminosity, and the Hubble diagram for QSOs. A.J.Pica, A.G.Smith (Rosemary Hill Obs., Univ. of Florida, Gainesville, FL, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.11-25 (1 Sept. 1983).
Photometric data for 130 quasars, BL Lac objects, and active galaxies have been obtained at the Rosemary Hill Observatory during a continuous 13 year monitoring program. These long-term optical records are employed in an effort to assess the physical and cosmological properties of quasi-stellar objects. Monochromatic flux densities at a standard emitted wavelength of 2500 Å are obtained from corrected *B* magnitudes, and long-term light curves are compiled for all objects. Three levels of activity are determined for each individual source. The Mean, Base, and Max flux densities are used to study QSOs in their average, quiescent, and active phases, respectively. Absolute intrinsic luminosities of all sources in the sample are computed from the monochromatic flux densities, using relativistic cosmological models. The amplitude of variability versus absolute luminosity relation is used to discriminate between two classes of QSO models. (54 refs.)

111259 VLBI maps of 3C 273 and 3C 345 at 2.3 GHz. M.H.Cohen, S.C.Unwin, K.R.Lind, A.T.Moffet, R.S.Simon (Owens Valley Radio Obs., California Inst. of Technol., Pasadena, CA, USA), P.N.Wilkinson, R.E.Spencer, R.S.Booth, G.D.Nicolson, A.E.Neill, L.E.Young.
Astrophys. J. (USA), vol.272, no.2, pt.1, p.383-9 (15 Sept. 1983).
Maps of the quasars 3C 273 and 3C 345 made at 2.3 GHz with an eight station VLBI array are presented. Five compact components spanning 45 milli-arcsec are seen in 3C 273, and four are seen in 3C 345. Comparisons with maps at higher and lower frequencies show that in both sources the core, which dominates the high-frequency 'core-jet' structure, is strongly self-absorbed at 2.3 GHz and below. The jet components have flat spectra, peaking between 2 and 5 GHz. In both sources the VLBI jet curves toward the direction of the arcsecond-scale outer jet. (15 refs.)

111260 Luminosity function of high-redshift quasars. B.Gaston (Dept. of Astron., Pennsylvania State Univ., Philadelphia, PA, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.411-33 (15 Sept. 1983).
Data from 10 different emission-line surveys are included in a study of the luminosity function of high-redshift quasars ($1.8 \leq z < 2.5$). Five of the surveys are analyzed through microdensitometric techniques, and the data for 70 new quasars are given including finding charts. The uncertainties in magnitudes, redshifts, and line equivalent widths are assessed. Criteria for selecting the redshift range $1.8 \leq z < 2.5$ are discussed, and the apparent magnitude distribution for quasars in that range is compared with that of UVX-selected quasars. The completion limits of the new surveys are examined in detail to establish the best sample for the study of the luminosity function. Data from the new surveys indicate a possible turndown at the faint end of the distribution. Total volume densities of quasars in the interval $1.8 \leq z < 2.5$ are calculated for each of three extrapolations of the trend of the data to low luminosities. These densities are compared with those of active galaxies and field galaxies at the present epoch. (31 refs.)

111261 Theoretical quasar emission-line profiles. II. Effects of source function variation and total thickness. R.C.Puetter, E.N.Hubbard (Center for Astrophys. & Space Sci., Univ. of California, San Diego, CA, USA).
Astrophys. J. (USA), vol.273, no.1, pt.1, p.36-43 (1 Oct. 1983).
For pt.I see ibid., vol.265, no.1, p.35-42 (1983). Continues the investigation of the effects of radiative transfer and individual cloud shape on the broad-line profiles observed in Seyfert 1 galaxies and quasars. The authors relax the assumption of Hubbard and Puetter (1983) that all the emission in a given line arises from a single portion of the curve of growth. They explicitly calculate aspect angle emission functions and are thereby able to prdict small line-to-line profile variations in a single object and present explicit aspect angle emission functions for use in future line profile studies for a wide range of source function variation and total optical depth. The authors propose a differential line profile test for cloud ensemble dynamics. (13 refs.)

111262 A single exhaust model for backward emission in Doppler quasars. J.V.Narlikar, K.Subramanian (Tata Inst. of Fundamental Res., Bombay, India).
Astrophys. J. (USA), vol.273, no.1, pt.1, p.44-57 (1 Oct. 1983).
Provides an astrophysical scenario for Hoyle's (1980) conjecture that quasars ejected at high velocities from active galactic nuclei radiate predominantly in a narrow backward cone. Backward emission is essential in a local Doppler theory in order to explain why no blueshifted quasars are seen. The mechanism suggested is an adaptation of the twin exhaust model of Blandford and Rees (1974). It is argued that a fast moving quasar encounters a strong ram pressure from the intergalactic medium in the forward direction which suppresses the forward exhaust. By contrast, the only exhaust from the object is along the line of least resistance lying in the backward direction. The model has several constraints from hydrodynamics, gravitation theory, and radiation requirements as well as the primary motivation that no blueshifted quasars are seen. (30 refs.)

111263 Millimeter and submillimeter observations of 3C 273. P.E.Clegg, W.K.Gear, P.A.R.Ade (Dept. of Phys., Queen Mary Coll., Univ. of London, London, England), E.I.Robson, M.G.Smith, I.G.Nolt, J.V.Radostitz, W.Glaccum, D.A.Harper, F.J.Low.
Astrophys. J. (USA), vol.273, no.1, pt.1, p.58-63 (1 Oct. 1983).
Reports the first detection of 3C 273 (1226+023) at wavelengths of 107, 240, and 400 μm together with contemporary measurements at 800 μm, 1.1, 1.9, 3.3, and 8.9 mm. These observations show that the continuum spectrum of 3C 273 can be extrapolated smoothly from the submillimeter to the infrared with a constant spectral index. There is no evidence of thermal emission from dust. The authors show that the spectrum is consistent with optically thin synchrotron emission from a relativistic beam at a small angle to the line of sight. (31 refs.)

111264 The radio structure of 3C 279. I.de Pater (Lunar & Planetary Lab., Univ. of Arizona, Tucson, AZ, USA), R.A.Perley.
Astrophys. J. (USA), vol.273, no.1, pt.1, p.64-9 (1 Oct. 1983).
Radio maps of the quasar 3C 279 have been made with resolutions between 0.06″ and 3.5″ at wavelengths of 1.3, 2.0, and 6 cm. At arcsecond resolutions, the source is a simple double with a component separation of 11.2″ in PA −35°. At higher resolutions, the northern component resolves out while the compact component consists of an unresolved flat-spectrum core with a jet extending 4.7″ in PA 205°. The jet is clearly resolved into numerous separate knots. This is no measurable Faraday depolarization in the resolved regions of the source, but a small rotation of the plane of the polarized emission is found in the unresolved core between 2 and 6 cm. The projected magnetic field is generally aligned parallel to the jet, and the spectral index of the jet emission steepens with increasing distance from the core. (24 refs.)

111265 On the dynamical structure of QSOs and the origin of emission clouds. G.A.Gurzadyan, V.G.Gurzadyan (Yerevan Polytech. Inst., Yerevan, Armenian SSR).
Astrophys. & Space Sci. (Netherlands), vol.94, no.1, p.31-42 (July 1983).
It is shown that emission lines, first of all the ultraviolet resonance double 2800 Mg II, can be used to decipher the internal dynamic structure of QSOs and active galactic nuclei. The electron temperatures of the emission regions of these objects are determined. A hypothesis is proposed explaining the observed broad profiles of the 2800 Mg II line as a summary effect of emission clouds with a Maxwellian velocity distribution. The main physical parameters of emission clouds in QSOs are obtained. A mechanism of formation of emission clouds is suggested. (30 refs.)

111266 Search for large-scale extension of the quasars 3C 273, 3C 345 and 3C 380. P.P.Kronberg (Scarborough Coll., Univ. of Toronto, Toronto, Canada), W.Reich.
Astron. & Astrophys. (Germany), vol.125, no.1, pt.2, p.146-9 (Aug. 1983).
Results of a further deep search for outer 'fossils' of earlier radio outbursts in the bright QSOs 3C 273, 3C 345 and 3C 380 are described—the first two of which have apparent superluminal motion. Multi-frequency, high dynamic range observations were made of and around the faint neighbour sources originally detected by Reich et al. (1980), using both the Effelsberg 100-m telescope and the VLA. The high resolution structure of the faint neighbour radio sources is determined, and a search for optical counterparts revealed only one certain identification—for 3C 345 SE. There is no firm evidence for extended radio features on a scale of a few hundred kpc to $\gtrsim 1$ Mpc for these QSOs. (4 refs.)

111267 Expected number of multiple QSOs from galaxy and QSO surface density data. J.A.Tyson (Bell Labs., Murray Hill, NJ, USA).
Astrophys. J. Lett. Ed. (USA), vol.272, no.2, pt.1, p.L41-4 (15 Sept. 1983).
What fraction of QSOs are gravitationally lensed? Recent data on galaxy counts, QSO counts, and radio and optical multiple QSO image surveys are examined. It is shown that these data are not consistent with the hypothesis that all QSOs are gravitationally lensed. Under the assumption that QSOs are at their redshift distance, a straightforward calculation based on seeing data, galaxy counts, and QSO counts yields a surface number density of multiple QSOs consistent with that found in existing surveys for multiple QSOs. This calculation suggests that the fraction of multiple QSOs will increase with QSO magnitude and that massive elliptical galaxies and clusters probably dominate as lenses. (24 refs.)

111268 3C 446. C.Barbieri, S.Cristiani, G.Romano.
I.A.U. Circ. (USA), no.3856, 1 pp. (29 Aug. 1983).
It is reported that between 4 and 11 August 1983 the quasar 3C 446 was at magnitude $B=15.1$, the brightest ever recorded for this object. (no refs.)

111269 Diffuse ultraviolet radiation in the intergalactic medium. P.M.Gondhalekar (Rutherford Appleton Lab., Chilton, Didcot, England).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.997-1007 (Sept. 1983).
The intensity of the diffuse ultraviolet radiation in the intergalactic medium (IGM) due to quasars is estimated. The diffuse radiation will be attenuated by hydrogen and helium in the galactic haloes in the IGM and the optical depth of cloudy IGM due to neutral hydrogen in galactic haloes is estimated. The stability and ionization balance of hydrogen clouds (Sargent et al. 1980) in this radiation field are considered and it is shown that with the reduced ionizing flux the clouds cannot be in ionization equilibrium. (46 refs.)

111270 A flare in the millimetre to IR spectrum of 3C 273. E.I.Robson (Div. of Phys. & Astron., Preston Polytech., Preston, England), W.K.Gear, P.E.Clegg, P.A.R.Ade, M.G.Smith, M.J.Griffin, I.G.Nolt, J.V.Radostitz, R.J.Howard.
Nature (GB), vol.305, no.5931, p.194-6 (15 Sept. 1983).
The authors report observations between February and May 1983 of a concurrent flare in the IR to near millimetre spectrum of 3C 273. These observations imply that the emission over this range of frequency originates in the same region of the source. The flare was seen to propagate to longer wavelengths while decaying at shorter wavelengths. The time scale of the flare is suggestive of an event within the central 0.1 pc of the source. (16 refs.)

111271 Observations of H 1414+089, QSO with extremely high velocity broad-absorption-line gas. C.Foltz, B.Wilkes, R.Weymann (Steward Obs., Univ. of Arizona, Tucson, AZ, USA), D.Turnshek.
Publ. Astron. Soc. Pac. (USA), vol.95, no.568, p.341-6 (June 1983).
The authors present spectroscopic observations of a faint optically-selected QSO with broad absorption features in its spectrum. The absorption troughs are extremely complex with both large- and small-scale structure. The low-velocity edge of the C IV trough is displaced blueward of the apparent emission line center by $\gtrsim 13000$ km s^{-1}. The data provide evidence that the gas responsible for the broad absorption trough is moving relative to the gas responsible for the broad emission lines by up to 66000 km s^{-1}. (10 refs.)

111272 Dynamics of the radiating gas in the quasar PHL 5200 and in kindred objects. V.P.Grinin (Crimean Astrophys. Obs., Acad. of Sci., USSR).
Sov. Astron. (USA), vol.26, no.6, p.647-50 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1070-4 (Nov.-Dec. 1982).
Recent interpretations of the peculiar resonance-line profiles in the spectrum of PHL 5200 have suggested that a radially symmetric, outward decelerating flow is issuing from the nucleus of this quasar. The braking mechanism is briefly discussed, and an explanation is offered for the unique emission spectrum. Qualitatively, however, the kinematic conditions in the PHL 5200 envelope resemble the velocity field in other quasar and Seyfert-nucleus envelopes. (12 refs.)

98.70Q X-ray and gamma-ray sources

111273 Reverse stellar evolution, stellar ablation, and the origin of gas in quasars. W.G.Mathews (Lick Obs., Univ. of California, Santa Cruz, CA, USA).
Astrophys. J. (USA), vol.272, no.2, pt.1, p.390-9 (15 Sept. 1983).
A stellar origin for the emission line gas and its confining medium in quasars and Seyfert galaxies is investigated. Radiative ablation of the photospheres by quasar radiation pressure seems preferable as an abundant and steady source of relatively low temperature gas. More radiant energy is incident on low-mass stars in the broad emission line region than they normally produce. These stars may absorb and mix the energy of hard quasar X-radiation deep within their fully convective interiors. As the total energy of the stars slowly increases by this process, they undergo reverse stellar evolution, expanding away from the lower main sequence toward regions of decreasing surface gravity in the H-R diagram. Eventually, radiative ablation of the inflated stars by hard quasar X-rays becomes possible. The hot ejecta from stellar collisions may provide gas for the intercloud medium, while radiative ablation is the source of cooler broad line gas. It is widely asserted that the near-infrared source IRS 16 is the stellar nucleus of our Galaxy. If correct, the unusual weakness of CO absorption, implying an abnormal deficiency of M-type dwarfs, suggests that reverse stellar evolution may have occurred in the Galaxy during a previous Seyfert-like episode. (39 refs.)

98.70V Background radiations

111274 On the anisotropy of the cosmological background matter and radiation distribution. II. The radiation anisotropy in models with negative spatial curvature. M.L.Wilson (Lab. for Extraterrestrial Phys., Goddard Space Flight Center, Greenbelt, MD, USA).
Astrophys. J. (USA), vol.273, no.1, pt.1, p.2-15 (1 Oct. 1983).
For pt.I see ibid., vol.243, no.1, p.14-25 (1981). The expected microwave background anisotropy is calculated on both large and small angular scales for various models with $\Omega_0=0.1$, including all effects of spatial curvature. Both adiabatic and isothermal fluctuations are considered, with power spectrum $|\delta_m(\tilde{k})|^2 \propto \tilde{k}^n$ initially. The adiabatic models can probably be ruled out on the basis of their large correlation length, but if only the microwave anisotropy is considered, models with $n \gtrsim 3$ are acceptable. The microwave anisotropy is below current upper limits for all values of n considered with isothermal initial conditions. (28 refs.)

111275 The anisotropy of the diffuse cosmic X-ray background. M.R.Issa, C.X.Xu, A.W.Wolfendale (Dept. of Phys., Univ. of Durham, Durham, England).
J. Phys. G (GB), vol.9, no.9, p.1151-8 (Sept. 1983).
In a previous paper Protheroe et al. (1980) used the Uhuru X-ray data of Schwartz (1979) to show that the anisotropy in the diffuse background for the energy range 2-7 keV was not inconsistent with that observed in the 2.7K relict radiation. The authors take more recent and extended data by Iwan et al. (1982) for the range 2-60 keV to make a new determination of the X-ray anisotropy. After eliminating the possibility that galactic effects are responsible or that the anisotropy is due to discrete extragalactic sources it is again found that there is no inconsistency with the 2.7K results, although the X-ray data are still not sufficiently accurate to enable a statement of clear consistency to be made. (14 refs.)

98.80 COSMOLOGY

(for observational cosmology, see 98.70V; for origin and evolution of galaxy, see 98.50)

111276 Pair correlations in an expanding Universe for a multicomponent system. H.E.Kandrup (Center for Relativity, Univ. of Texas, Austin, TX, USA).
Astrophys. J. (USA), vol.272, no.1, pt.1, p.1-10 (1 Sept. 1983).
Fall and Saslaw (1976) have derived an equation for the growth of pair correlations in an expanding Universe of identical self-gravitating point masses which is correlation-free at some initial time. Their equation is rigorously true for the earliest stages of growth, assuming only that the system is spatially homogeneous and isotropic, and that it is characterized in the 'comoving frame' by a Maxwellian distribution of velocities. The author generalizes their analysis to the case of a multicomponent system of particles with different masses, each species of which is characterized by a Maxwellian distribution at the same temperature. Here there are two types of pair correlations to consider, namely among members of the same species and among members of different species. The general behavior may be understood most readily by considering the covariance functions, which assume very simple forms. (7 refs.)

111277 A general solution of the Einstein equations with a time singularity. V.A.Belinskii, I.M.Khalatnikov, E.M.Lifshitz (L.D. Landau Inst. for Theoretical Phys., Acad. of Sci., Moscow, USSR).
Adv. Phys. (GB), vol.31, no.6, p.639-67 (Nov.-Dec. 1982). [received: Sept. 1983]
This paper is a concluding review exposition of the investigations aimed at the construction of a general cosmological solution of the Einstein equations with a singularity in time; thus it is a direct continuation of the previous (1970) paper by the authors. A detailed description is given of the analysis which leads to the construction of such a solution, and of its properties. (12 refs.)

111278 Equation of state and equation symmetries in cosmology. M.Szydlowski (Dept. of Philosophy, Pontifica Acad. of Cracow, Cracow, Poland), M.Heller.
Acta Phys. Pol. B (Poland), vol.B14, no.8, p.571-80 (Aug. 1983).
Symmetry groups of Friedman equations both without and with dissipation, and of Bianchi type I equations with dissipation are discussed. It is shown that the symmetry groups of these equations correctly single out corresponding equations of state. (11 refs.)

111279 Fluctuations in the inflationary Universe. S.W.Hawking (DAMTP, Cambridge, England), I.G.Moss.
Nucl. Phys. B, Part. Phys. (Netherlands), vol.B224, no.1, p.180-92 (29 Aug. 1983).
In the usual treatment of the inflationary Universe, it is assumed that the expectation value of some component of the Higgs field develops a non-zero symmetry breaking value Φ_0. However, in the models normally considered, the expectation value of Φ will be zero at all times because Φ and $-\Phi$ are equally probable. To overcome this difficulty, the authors calculate the effective action as a function of $\langle\Phi^2\rangle$ rather than $\langle\Phi\rangle$. This also solves the infrared problem associated with a Coleman-Weinberg condition in de Sitter space. The expectation value of Φ^2 grows linearly with time at first and then as $(t_2-t)^{-1}$. The irregularities in the resulting Universe are smaller than those predicted by previous authors, though in the case of the standard SU(5) GUT they are still bigger than the limit set by the microwave background. (24 refs.)

111280 Quantization in the large. D.M.Greenberger (City Coll., City Univ. of New York, New York, NY, USA).
Found. Phys. (USA), vol.13, no.9, p.903-51 (Sept. 1983).
A model theory is constructed that exhibits quantization on a cosmic scale. A holistic rationale for the theory is discussed. The theory incorporates a fundamental length, of cosmic size, and preserves the weak, geometrical equivalence principle. The momentum operator is an integral, nonlocal, naturally contravariant operator, in contrast to the usual quantum case. In the limit of high quantum numbers the theory reduces to classical physics, giving rise to a world which is quantized both on the microscopic and cosmic scale, each of which passes over to the usual macroscopic, continuous, classical, world in the high n limit. The theory is applied to two experimental situations, absorption lines in high-z quasars and elliptical rings around normal galaxies, with suggestive but not definitive results. (22 refs.)

111281 The anthropic principle and the actual size of the Universe. V.De Sabbata, M.Gasperini (Istituto de Fisica, Univ. di Ferrara, Italy).
Lett. Nuovo Cimento (Italy), vol.37, ser.2, no.17, p.605-8 (27 Aug. 1983).
It is suggested that the equality of the recession velocity and the escape velocity of matter in our Universe can be explained by using the spin-torsion interactions, without invoking the anthropic principle. (16 refs.)

111282 Three-dimensional numerical model of the formation of large-scale structure in the Universe. A.A.Klypin, S.F.Shandarin (Keldysh Inst. of Appl. Maths., Acad. of Sci., Moscow, USSR).
Mon. Not. R. Astron. Soc. (GB), vol.204, no.3, p.891-907 (Sept. 1983).
The first results of numerical fully three-dimensional simulations of formation and evolution of the large-scale structure of the Universe are presented. The simulations are carried out in the framework of the adiabatic scenario of galaxy formation. The model contains $32^3=32768$ collisionless particles interacting only gravitationally. Equal mass particles are moving in a collective gravitational field which is smoothed at small scales. Evolution of perturbations is followed in an expanding cosmological model. The numerical procedure starts at $z_{\mathrm{start}} \simeq 5.25$, when $(\delta\rho/\rho)_{\mathrm{ro}} \simeq 0.22$ and ${}_{\mathrm{ro}}=5h_{100}{}^{-1}$ Mpc is the cell length. The two-point correlation function is calculated. (31 refs.)

111283 Three-dimensional simulation of large-scale structure in the Universe. J.Centrella (Dept. of Astron., Univ. of Illinois, Urbana, IL, USA), A.L.Melott.
Nature (GB), vol.305, no.5931, p.196-8 (15 Sept. 1983).
Three-dimensional numerical simulations of the nonlinear growth of adiabatic perturbations in collisionless matter demonstrate that a cellular structure develops in the Universe. This dark matter collapses into interconnecting dense regions surrounding large voids, or low density regions. The simulations show that the interconnecting dense regions contain both filamentary and flat, pancake-shaped structures. The low-density voids are approximately spherically symmetric in shape. The covariance function has a power law form at small radii, with anticorrelation found just beyond the break and no sizeable features at larger radii. (40 refs.)

111284 Exact rotating and expanding radiation-filled universe. K.Rosquist (Dept. of Appl. Math., Queen Mary Coll., London, England).
Phys. Lett. A (Netherlands), vol.97A, no.4, p.145-6 (22 Aug. 1983).
An exact rotating and expanding solution of the Einstein field equations without cosmological constant is given. The solution represents a Bianchi type

VI_0 spatially homogeneous universe filled with radiation having the equation of state $p=\rho/3$. (7 refs.)

111285 **Where has the four dimensionality come from?.** H.Ishikawa (Dept. of Phys., Nagoya Univ., Nagoya, Japan).
Prog. Theor. Phys. (Japan), vol.69, no.6, p.1837-9 (June 1983).
A five dimensional gravitation model is examined and it is shown that the smallness of extra-dimension is a consequence of the Universe being small in the past. (2 refs.)

111286 **Entropy from extra dimensions.** E.Alvarez (Lyman Lab. of Phys., Harvard Univ., Cambridge, MA, USA), M.Belen Gavela.
Phys. Rev. Lett. (USA), vol.51, no.10, p.931-4 (5 Sept. 1983).
The phenomenon of 'dynamical compactification' in a universe with $4+n_c$ dimensions is studied, and it is found that if the whole process is adiabatic, entropy is pumped into the effective four-dimensional universe. Some cosmological consequences of this fact are discussed. (7 refs.)

111287 **Cluster analysis of the nonlinear evolution of large-scale structure in an axion/gravitino/photino-dominated Universe.** A.L.Melott (Dept. of Phys. & Astron., Univ. of Pittsburgh, Pittsburgh, PA, USA), J.Einasto, E.Saar, I.Suisalu, A.A.Klypin, S.F.Shandarin.
Phys. Rev. Lett. (USA), vol.51, no.10, p.935-8 (5 Sept. 1983).
The authors consider nonlinear evolution of the inflationary scale-free spectrum of adiabatic density perturbations in (1) a neutrino-dominated Universe (sharp short-wavelength cutoff), and (2) an axion-, gravitino-, or photino-dominated Universe (some small-scale power). In (2) galaxy formation begins long before the present (as defined by covariance function), resolving a possible problem in (1). Both models are found to be acceptable upon cluster analysis. The authors believe that a new picture, based on (2), merits consideration. (54 refs.)

111288 **Problems with the new inflationary Universe.** J.D.Breit, S.Gupta, A.Zaks (Inst. for Advanced Study, Princeton, NJ, USA).
Phys. Rev. Lett. (USA), vol.51, no.11, p.1007-9 (12 Sept. 1983).
It is demonstrated that in the new-inflationary-Universe scenario based on a Coleman-Weinberg-type potential all the bubbles evolve through the $SU(4)\otimes U(1)$ local minimum. The transition from this local minimum to the $SU(3)\otimes SU(2)\otimes U(1)$ global minimum is first order, and so the scenario does not solve all of the cosmological problems. (9 refs.)

111289 **On the possibility of a test of the cosmology of asymptotically free SU(5) theory.** O.K.Kalashnikov (P.N. Lebedev Phys. Inst., Moscow, USSR), M.Yu.Khlopov.
Phys. Lett. B (Netherlands), vol.127B, no.6, p.407-12 (11 Aug. 1983).
Asymptotically free models of grand unification predict the existence of metastable superheavy fermions determining the evolution of the very early Universe. The estimates of the influence of such fermions on the baryon asymmetry of the Universe, on primordial black hole formation, and on the abundance of light elements provide stringent restrictions both on the parameters of grand unified models and on possible scenarios of the evolution of the very early Universe. (13 refs.)

111290 **Scalar Green function in Nardone's cosmological model.** P.Spindel (Univ. de l'Etat a Mons, Mons, Belgium).
Phys. Lett. B (Netherlands), vol.127B, no.6, p.413-14 (11 Aug. 1983).
Closed expressions for the Green functions of a free scalar field in Nardone's cosmological model (1983) are obtained by summing modes corresponding to a vacuum state defined in the far past. (5 refs.)

111291 **Inflation in a shear- or curvature-dominated Universe.** G.Steigman, M.S.Turner (Astron. & Astrophys. Center, Enrico Fermi Inst., Univ. of Chicago, Chicago, IL, USA).
Phys. Lett. B (Netherlands), vol.128B, no.5, p.295-8 (1 Sept. 1983).
The authors show that new inflation occurs even if the Universe is shear- or (negative) curvature-dominated when the phase transition begins. In such situations the size of a causally coherent region, after inflation, is only slightly smaller (by powers, but not by exponential factors) than the usual result. The creation and evolution of density perturbations is unaffected. This result is in marked contrast to 'old' inflation, where shear-or curvature-domination could quench inflation. (19 refs.)

111292 **Alternative descriptions of the discrete mixmaster universe.** Y.Elskens (Faculte des Sci., Univ. Libre de Bruxelles, Bruxelles, Belgium).
Phys. Rev. D (USA), vol.28, no.4, p.1033-5 (15 Aug. 1983).
In the framework of Belinskii, Khalatnikov, and Lifshitz's (1970) discretization of the mixmaster universe, a new representation is proposed admitting a transparent dynamics. (9 refs.)

111293 **Parameters of a neutrino-dominated Universe and GUT cosmology.** A.G.Doroshkevich, M.Yu.Khlopov.
Pis'ma v Astron. Zh. (USSR), vol.9, no.6, p.323-6 (1983). In Russian. English translation in: *Sov. Astron. Lett. (USA)*
Investigates the agreement between GUT values of the neutrino mass and observed parameters of the Universe. The possibilities put severe restrictions on GUTs. (19 refs.)

111294 **The dynamical role of a primordial electromagnetic field in spatially homogeneous, diagonal Bianchi type I-IX cosmologies.** V.A.Ruban (Leningrad Inst. of Nuclear Phys., Leningrad, USSR).
Sov. Astron. (USA), vol.26, no.6, p.632-8 (Nov.-Dec. 1982). Translation of: *Astron. Zh. (USSR)*, vol.59, no.6, p.1044-54 (Nov.-Dec. 1982).
The possible structure of a sourceless primordial electromagnetic field (which is admissible only for class *A* diagonal Bianchi metrics), its dynamical behavior, its role near the initial singularity, and its influence on the isotropization process are examined in terms of homogeneous, anisotropic cosmologies. In Bianchi type VI_0, VII_0 models a pure magnetic primordial field will cause a new form of oscillatory asymptotic approach to the singularity $\tau=0$, but in types VIII, IX the coupled electromagnetic field will have little effect on the 'mixmaster' vacuum regime. The primordial magnetic field hypothesis is compatible only with parabolic, isotropizing, quasi-Euclidean models (primarily Bianchi types I, VII_0), provided the energy density is near-critical ($\Omega=\epsilon_0/\epsilon_c\approx 1$). (61 refs.)

BIBLIOGRAPHY INDEX

^{31}P NMR spectroscopy, non-biological aspects, (339 refs.) 105354
Active galactic nuclei, (96 refs.) 111222
Active galactic nuclei, (54 refs.) 111241
Ag$_c$Mn$_{1-c}$ spin glass, electronic struct, (50 refs.) 108273
Aromatic dipeptides, flexibility, (63 refs.) 106445
Artificial satellite motion, (101 refs.) 110858
Asteroids and comets, (127 refs.) 110958
Atom-electron collisions, (76 refs.) 106608
Atomic beam scattering from single crystal surfaces, (245 refs.) 109089
Atomic collisions in fusion, (111 refs.) 107336
Atomic defects and diffusion in metals, (69 refs.) 108038
Auroral aeronomy, (82 refs.) 110757
Baryon spectroscopy, (408 refs.) 105595
Binuclear transition metal compounds, symm. breaking, (82 refs.) 106282
Biomagnetic geomagnetism, (65 refs.) 110064
Bound nucleon residual interaction, two nucleon matrix elements from transfer experiments, (157 refs.) 105755
Bremsstrahlung isochromatic spectroscopy, (109 refs.) 109095
Broken ergodicity in condensed matter physics, (106 refs.) 105220
CANDU fuel and fuel cycles, AECL publications 105056
Carbon tetrachloride glow discharges, spectra, (59 refs.) 107438
Cementite decomposition in steel under plastic deformation, (58 refs.) 109212
Classical fluids, critical fluctuation scaling, (53 refs.) 105247
Classical radiation zeros in gauge-theory amplitudes, (61 refs.) 105550
Collisional broadening of nonlinear optical resonances, (99 refs.) 106539
Conduction plane disorder in beta-Al$_2$O$_3$-Na$_2$O, (89 refs.) 108034
Confinement of ions for collision studies, (60 refs.) 107435
Cosmic rays modulation/anomalous component, (87 refs.) 110826
Cosmological EM fields, (61 refs.) 111294
Coupled fields and nonclassical continuous media, (66 refs.) 105110
Cyanogen, outermost valence orbitals, photoelectron investigation, (76 refs.) 106497
Diamond polishing processes, (71 refs.) 109550
Diffusion-induced changes in defect structure, (46 refs.) 108012
Diffusive shock acceleration of energetic particles in tenuous plasma, (75 refs.) 107348
Discussion of several analytical approximate expressions for the eigenvalues of the bounded harmonic oscillator and hydrogen atom, (57 refs.) 105140
Dwarf novae photometry, (46 refs.) 111106
Earth radiation budget, (91 refs.) 110523
Electric giant resonances, (63 refs.) 105816
Electrical conductivity meas. of liquid metals and semiconductors, (62 refs.) 105339
Electrical resistivity of binary alloy systems, (408 refs.) 105043
Electrochemical conditions in crevices, pits and cracks, (83 refs.) 109559
Electron impact excitation of ions, (76 refs.) 106609
Electron-impact ionization of ions, (110 refs.) 106610
Electron-ion recombination, (146 refs.) 106586
Electron precipitation and related aeronomy of the Jovian thermosphere and ionosphere, (80 refs.) 110961
Electrostatic double layers in laser produced plasmas, (73 refs.) 107411
EM wave propagation in regular waveguides, (76 refs.) 110789
Equation of state for saturated vapour-liquid equilibrium, (90 refs.) 107857
Event-related potentials during naming and mental rotation, (54 refs.) 110024
Fatigue cracks subjected to biaxial stress, (77 refs.) 107058
Fe, finite temp. magnetism, spin fluctuation theory, (69 refs.) 108634
Flood frequency analysis, (130 refs.) 110499
Flowing afterglow plasma ion-ion recombination, (70 refs.) 107337
Fluid physics under reduced gravity, (63 refs.) 107229
Force fields for large molecules, (100 refs.) 106529
Forced reconnexion by fast magnetosonic waves in a current sheet with stagnation-point flows, (61 refs.) 107362
Fractography recent developments, (67 refs.) 109633
Frozen-core approximation with a nonempirical polarisation potential: the sodium isoelectronic sequence, (58 refs.) 106293
GaAs and AlAs mixed crystals electrical transport properties, (76 refs.) 108417
GaAs luminescence properties, changes due to external effects, (80 refs.) 108994
Galactic cosmic rays, (102 refs.) 110820
Galaxy magnitude-redshifts, (57 refs.) 111227
Geological record of climatic change, (440 refs.) 110646
Gravitational radiation, (66 refs.) 105183
Gravitational waves, numerical methods, (82 refs.) 105186
Groundwater, (111 refs.) 110505
Heat-stress proteins and thermal resistance in rat mammary tumor cells, (58 refs.) 109974
Heavy particle impact excitation of atoms, angular correlation studies, (96 refs.) 106540
Heliosphere magnetic fields and plasma, (242 refs.) 110841
Heliosphere shocks and cosmic rays, (145 refs.) 110822
Hydrodynamic modelling in hydrology, (183 refs.) 110503
III-V semiconductors with Sn impurities, lattice vibration, (73 refs.) 107837
Induced currents in submarine cables, (92 refs.) 110296
Inelastic ion-ion and electron-ion collisions, (70 refs.) 106611
Inner planets—aeronomy, (159 refs.) 110954
Interdisciplinary science-humanities course, (5 refs.) 105085
Interface energetics in metals and alloys, (121 refs.) 108114
Interpretation methods for magnetometer arrays, (115 refs.) 110297
Interstellar C chain, (56 refs.) 111172
Ion collisions in astrophysics, (107 refs.) 110905
Ion sputtering applied to biomaterials, (59 refs.) 109549
Ionospheric electrodynamics and irregularities, (230 refs.) 110790
Isotropic turbulence structure, (52 refs.) 107108
Jupiter magnetosphere, (263 refs.) 110966
K^0-$\bar{K}^0$ system fundamental parameters, (69 refs.) 105635
Lipid bilayers, gel-fluid phase transition, (59 refs.) 109980
Liquid film mass transfer coefficients, (54 refs.) 107237
Liquid water, molecular dynamics, (123 refs.) 107511
Lower galactic halo interstellar matter, (104 refs.) 111168
LWR fuel post-irradiation analysis, Benchmark data, (62 refs.) 105980
Magnetoelectrolysis, (101 refs.) 109758
Magnetosphere, (178 refs.) 110792
Magnetosphere energy transfer, (441 refs.) 110811
Magnetosphere MHD waves, (338 refs.) 105055
Magnetosphere particles, (271 refs.) 110809
Magnetosphere plasma boundaries and shocks, (273 refs.) 110810
Matrix isolated molecules, infrared studies of site structure and dynamics vibrational spectra;, (92 refs.) 106422
Mechanics of aerosols in reactor safety, (60 refs.) 106114
Medical lasers, (89 refs.) 110114
Megalithic lunar sightlines, (164 refs.) 110934

Metallurgy and applications of beryllium, (88 refs.) 109185
Metre-wave solar radio events, (80 refs.) 110931
Middle atmosphere chemistry, (222 refs.) 110749
Middle atmosphere dynamics, (125 refs.) 110750
Molecular structure by Raman resonance spectroscopy, (102 refs.) 106331
Ne$_2$, interatomic interaction energy, perturbation theory calcs, (72 refs.) 106526
Neutron star magnetic field, (75 refs.) 111124
Neutron star structure, (61 refs.) 111120
Nondestructive inspection using multitransducer eddy current devices, (59 refs.) 109674
Nuclear dynamics in resonant electron-molecule scattering beyond the local approximation: the 2.3-eV shape resonance in N$_2$, (73 refs.) 106617
Nuclear moments of ^{9}Li, (65 refs.) 105881
Organic films on atmospheric particles, (155 refs.) 110596
Organic material in troposphere, (215 refs.) 110597
Outer planets satellites, (111 refs.) 110965
Palaeomagnetism, (60 refs.) 110943
Pd:H, partial excess thermodynamic props, (53 refs.) 107985
Photoabsorption and photoionization of HD, (62 refs.) 106516
Planetary atmospheres, (165 refs.) 110812
Planetary atmospheres, (254 refs.) 110945
Planetary lightning, (108 refs.) 110595
Planetary magnetospheres plasma waves, (514 refs.) 110950
Planetary radar astronomy, (104 refs.) 110948
Planetary rings, (304 refs.) 110947
Plasma polymerisation of ethene, (78 refs.) 109738
Plastics for high-power laser applications, (51 refs.) 106792
Polar and auroral phenomena, (382 refs.) 110791
Poly-1,6-heptadiyne, freestanding film, elec. cond, (50 refs.) 108577
Polydiacetylenes, photocarrier generation, (50 refs.) 108470
Positron physics, (170 refs.) 109041
Potential energy curves for dissociative recombination, (84 refs.) 106620
Prediction of critical heat flux in flow boiling at low qualities, (65 refs.) 106117
Raman difference spectroscopy, (50 refs.) 105387
Researching and restoring pioneer talking pictures: the 70th anniversary of the theatrical release of Kinetophone, (53 refs.) 105406
Rock magnetism, (120 refs.) 110366
Rock varnish dating, (69 refs.) 110344
Roentgen stereophotogrammetry in orthopaedics, (58 refs.) 110149
Saturn magnetosphere, (98 refs.) 110983
Smectite to illite conversion in hydrothermal systems, (58 refs.) 106147
Snow and ice, (371 refs.) 110506
Solar activity, (186 refs.) 111019
Solar cosmic ray particles, (197 refs.) 110825
Solar system origin, (188 refs.) 110941
Solar wind and cycles, (83 refs.) 110840
Solid electrolyte batteries and fast ion conducting glasses. Factors affecting a proposed merger, (52 refs.) 109880
Solubility of O$_2$ and O$_3$ in liquids, (106 refs.) 105041
Space-time symmetries and photon selection rules, (55 refs.) 105076
Speleothems, travertines, and paleoclimates, (66 refs.) 110343
Stellar temperature scale, (109 refs.) 105086
Stochastic processes in neurophysiology: transformation from point to continuous processes, (63 refs.) 109996
Surface damage of Cu/Ni alloys, (64 refs.) 107784
Surface water hydrology, (165 refs.) 110501
Surface water hydrology models, (113 refs.) 110500
Synchrotron radiation application to EXAFS and SEXAFS, (79 refs.) 109049
Tectonics of Acadian Orogeny, (90 refs.) 110357
Terrestrial planets—geology, (282 refs.) 110946
Thermal conductivity of inert gases over a wide temperature range, (84 refs.) 107318
Thermal shock in nuclear reactors, (61 refs.) 106115
Thermoelasticity problems, (64 refs.) 105112
Thermosphere—composition, (195 refs.) 110747
Thermospheric dynamics, (290 refs.) 110746
Toughening of structural ceramics, (90 refs.) 109319
Transient annealing of ion implanted gallium arsenide, (62 refs.) 107757
Tunable diode lead chalcogenide lasers, (81 refs.) 106765
Type I planetary nebulae and bipolar nebulae, (58 refs.) 111196
Ultrashort laser pulse generation, (490 refs.) 106789
Unsaturated soil moisture flow, (105 refs.) 110504
Urban hydrology, (575 refs.) 110502
Use of strain gauges for biometrics in Europe, (63 refs.) 110217
Velocity dependence of Rydberg $n \to n'$ charge transfer cross sections, (51 refs.) 106576
Vibrational excitation in ion-molecule collisions, (52 refs.) 106543
Vibrational spectra and conformational analysis of substituted three membered ring compounds, (158 refs.) 106632
Vibrational spectra of small matrix isolated molecules, (276 refs.) 106530
Vitamin B$_{12r}$ dioxygen adduct, single cryst. EPR, (59 refs.) 108757
Vortex ring shedding flowmeter, (90 refs.) 107291
Weak radiation collisional redistribution, (59 refs.) 106542
Zeeman atomic absorption spectroscopy, (76 refs.) 105384

BOOK INDEX

Atmosphere-ocean dynamics; A.E.Gill, [New York, USA: Academic Press 1982] 105050
Basaltic volcanism on the terrestrial planets; *W.M.Kaula, J.W.Head III, R.B.Merrill, R.O.Pepin, S.C.Solomon, D.Walker, C.A.Wood (editor/s),* [New York, USA: Pergamon 1981] 105038
BMS meteor observer's handbook. Vol.II. Telescopic meteor work. 6th edition; R.A.Mackenzie, [London, England: Mackenzie 1983] 110998
Constrained dynamics with applications to Yang-Mills theory, general relativity, classical spin, dual string model; K.Sundermeyer, [Berlin, Germany: Springer-Verlag 1982] 105039
Elastic media with microstructure I. One-dimensional models; I.A.Kunin, [Berlin, Germany: Springer-Verlag 1982] 105051
Fundamentals of molecular spectroscopy. Third edition; C.N.Banwell, [Maidenhead, Berks., England: McGraw-Hill 1983] 105052
Geoelectromagnetic investigation of the Earth's crust and mantle; I.I.Rokityansky, *N.L.Chobotova, G.M.Pestryakov, M.N.Pristay, B.G.Shilman (translator/s),* [Berlin, Germany: Springer-Verlag 1982] 105054
Maximum principle in finite element models for convection-diffusion phenomena; T.Ikeda, [Amsterdam, Netherlands: North-Holland 1983] 105286
Physics of vibrations and waves. 3rd edition; H.J.Pain, [Chichester, West Sussex, England: Wiley 1983] 105131
Thunderstorms: A social scientific and technological documentary. Vol. 2. Thunderstorm morphology and dynamics; *E.Kessler (editor/s),* [Washington, DC, USA: U.S. Government Printing Office 1982] 105053
Vibrational spectra and structure. A series of advances. Vol.12; *J.R.Durig (editor/s),* [Amsterdam, Netherlands: Elsevier 1983] 105049 (introductory abstract), 105387, 106331, 106422, 106529—30, 106632

CONFERENCE INDEX

162nd Meeting of the American Astronomical Society; St. Paul, MN, USA, 19-22 June 1983, [1983] 105012 (introductory abstract),
18th IAU General Assembly; Patras, Greece, 17-26 Aug. 1982, *R.M.West (editor/s),* [Dordrecht, Netherlands: Reidel 1983] 105030 (introductory abstract),
Air pollution meteorology; San Antonio, TX, USA, 12-15 Jan. 1982, *(American Meteorological Soc.; Air Pollution Control Assoc)* [Boston, MA, USA: American Meteorological Soc. 1983] 105036 (introductory abstract),
Alloy phase diagrams; Boston, MA, USA, Nov. 1982, *L.H.Bennett, T.B.Massalski, B.C.Giessen (editor/s),* [New York, USA: North-Holland 1983] 105048, 107830, 107883, 108101, 108712, 109236—44
Applied electromagnetics; Florence, Italy, 4-6 Oct. 1982, [May-June 1983] 105009 (introductory abstract), 105170, 106660, 109971, 110077, 110079—80, 110112—13
Biostereometrics '82; San Diego, CA, USA, 24-27 Aug. 1982, [1983] 105016 (introductory abstract), 105393, 109976, 110015, 110067—71, 110104—5, 110117—35, 110149—56, 110213—14, 110235, 110245—53
Cathode Workshop; Fort Monmouth, NJ, USA, 23-26 March 1982, [May-June 1983] 105010 (introductory abstract), 108129, 108507, 108576, 109059—62, 109069, 109076, 109090, 109115, 109167
Chemistry of materials at high temperatures; Harwell, Oxon., England, 7-10 Sept. 1981, [1982] 105315
Circuits and systems; Toledo, OH, USA, 4-5 Aug. 1980, *A.R.Thorbjornsen, G.W.Zobrist (editor/s),* [North Hollywood, CA, USA: Western Periodicals 1980] 110075
Computers in cardiology; Seattle, WA, USA, 12-15 Oct. 1982, *(IEEE)* [Silver Spring, MD, USA: IEEE Computer Society Press 1983] 109949, 110013, 110111, 110174, 110226—30, 110271—3
Crime countermeasures and security; Lexington, KY, USA, 11-13 May 1983, *(Univ. Kentucky; IEEE) J.S.Jackson, R.W.De Vore (editor/s),* [Lexington, KY, USA: Univ. Kentucky 1983] 106896
Electro '81; New York, USA, 7-9 April 1981, [El Segundo, CA, USA: Electron. Conventions 1981] 105370, 106893—5, 106908—9, 110733
Excimer lasers; Incline Village, NV, USA, 10-12 Jan. 1983, *(Opt. Soc. America; Air Force Office Sci. Res.; IEEE)* [1983] 106364, 106501, 106509, 106740, 106815, 109763
Fifteenth Hawaii International Conference on System Sciences 1982; Honolulu, HI, USA, 6-8 Jan. 1982, *(Univ. Hawaii; Univ. Southwestern Louisiana) W.Riddle, K.Thurber, P.Keen, R.H.Sprague Jr., B.Shriver, T.M.Walker, R.R.Grams (editor/s),* [HI, USA: Hawaii Int. Conference Syst. Sci. 1982] 110009—12, 110039, 110198
Galaxies internal kinematics and dynamics; Besancon, France, 9-13 Aug. 1982, *E.Athanassoula (editor/s),* [Dordrecht, Netherlands: Reidel 1983] 105029 (introductory abstract),
Gamma-ray astronomy; Ottawa, Canada, 16 May-2 June 1982, *(COSPAR; IAU)* [1983] 105015 (introductory abstract),
Geoscience and remote sensing; Munich, Germany, 1-4 June 1982, *(IEEE)* [1982] 110372—9, 110702—17
Gravitational radiation; France, 2-21 June 1982, *N.Deruelle, T.Piran (editor/s),* [Amsterdam, Netherlands: North-Holland 1983] 105034 (introductory abstract), 105182—93, 105213—19
Heavy ion collisions; La Rabida, Spain, 7-18 June 1982, *G.Madurga, M.Lozano (editor/s),* [Berlin, Germany: Springer-Verlag 1982] 105028 (introductory abstract), 105725—9, 105737—9, 105756, 105787, 105799, 105822, 105834, 105837, 105875, 105926—33
Laser-solid interactions and transient thermal processing of materials; Boston, MA, USA, 1-4 Nov. 1982, *(US DOE) J.Narayan, W.L.Brown, R.A.Lemons (editor/s),* [New York, USA: Elsevier 1983] 106980, 107559, 107753, 107757—60, 107768—70, 107788—9, 107890, 108063, 108240—1, 108348, 108582, 109033, 109147, 109177, 109372—3, 109604
Life sciences and space research XX(1); Ottawa, Canada, 16 May-2 June 1982, *(COSPAR)* [1983] 110195 (introductory abstract),
Life sciences and space research XX(2); Ottawa, Canada, 16 May-2 June 1982, *(COSPAR)* [1983] 110196 (introductory abstract),
Light ion reaction mechanisms; Osaka, Japan, 16-20 May 1983, *H.Ogata, T.Kammuri, I.Katayama (editor/s),* [Osaka, Japan: Osaka University 1983] 105721—4, 105742, 105748, 105786, 105798, 105806—7, 105817—21, 105825—33, 105836, 105868—74, 105882—3, 105887—90, 105917—25
Materials sciences under microgravity; Madrid, Spain, 5-8 April 1983, *(ESA; UPM; ELGRA; COSPAR)* [Paris, France: ESA 1983] 105032 (introductory abstract), 105327, 106735, 106949, 106957, 107121, 107156—61, 107229—32, 107581—2, 107884—9, 108003—4, 108123—7, 109127, 109140—2, 109190, 109245—6, 109276, 109708
Measurement methods and technology; Berlin, Germany, 24-28 May 1982, *K.Havrilla, J.Solt, T.Kemeny (editor/s),* [Amsterdam, Netherlands: North-Holland 1983] 105310, 105320, 106892, 107289—307
Medical picture archiving and communication systems; Kansas City, MO, USA, 22-25 May 1983, *(SPIE; IEEE)* [New York, USA: IEEE 1983] 110144
Mercuric iodide nuclear radiation detectors; Jerusalem, Israel, 6-8 June 1982, [15 July 1983] 105014 (introductory abstract), 106201—2, 106217—33, 110907—8

Microelectronics research; College Station, TX, USA, 25-27 May 1983, *(IEEE; Int. Soc. Hybrid Microelectron) N.R.Strader II (editor/s),* [New York, USA: IEEE 1983] 108545, 109176

Microscopic theories of nuclear collective motions; Kyoto, Japan, 12-16 July 1982, *(Yukawa Found.; Yamada Sci. Found)* [1983] 105008 (introductory abstract), 105720, 105754, 105759, 105762−72, 105774−80, 105813−16

Midcon 82; Dallas, TX, USA, 30 Nov.-2 Dec. 1982, [El Segundo, CA, USA: Electron. Conventions 1982] 106937

Neutron scattering in condensed matter; Hakone, Japan, 1-4 Sept. 1982, [May 1983] 105020 (introductory abstract), 105418−19, 105435, 106194−9, 106208−14, 106245, 106688, 107148, 107486−90, 107514−16, 107565−6, 107928, 107953−6, 107967, 108315, 108362, 108595, 108638, 108645−51, 108660, 108664−77, 108688−9, 108707−8, 108719, 109307, 109963−5, 109982

Nuclear techniques in geothermal investigations; Vienna, Austria, 3-6 Nov. 1981, [1983] 105018 (introductory abstract),

Optical glass research; Jena, Germany, 1982, [1983] 105025 (introductory abstract), 106769, 106834, 106836−7, 108428, 108917, 108977, 108986, 109808, 109880

Optical techniques for remote probing of the atmosphere; Incline Village, NV, USA, 10-12 Jan. 1983, *(Opt. Soc. America; Air Force Office Sci. Res)* [1983] 106704, 109931, 110648, 110663−80, 110751, 110920

Orogenic belts palaeomagnetism; Leeds, England, 1982, [1983] 105023 (introductory abstract),

Physics and chemistry of semiconductor interfaces; Santa Fe, NM, USA, 25-27 Jan. 1983, [July-Sept. 1983] 105017 (introductory abstract), 105379, 107494, 107995, 108069−73, 108076, 108133−4, 108159−62, 108198−202, 108215−21, 108491−9, 108509−14, 108524, 108529−35, 108550−1, 108559−62, 109093−4, 109542−5

Physics of ion-ion and electron-ion collisions; Baddeck, NS, Canada, 13-26 Sept. 1981, *F.Brouillard, J.W.McGowan (editor/s),* [New York, USA: Plenum 1983] 105031 (introductory abstract), 106581−2, 106586, 106608−11, 106620, 107336−7, 107435, 110905

Planetary nebulae; London, England, 9-13 Aug. 1982, *D.R.Flower (editor/s),* [Dordrecht, Netherlands: Reidel 1983] 105027 (introductory abstract),

Plant startup and operations in the '80s; Scottsdale, AZ, USA, 1-3 Aug. 1983, [1983] 105022 (introductory abstract), 105949−51, 105967−78, 106087−105, 106127−44, 106154−6, 106176

Point defects and defect interactions in metals; Kyoto, Japan, 16-20 Nov. 1981, *J.-I.Takamura, M.Doyama, M.Kiritani (editor/s),* [Amsterdam, Netherlands: North-Holland 1982] 105037 (introductory abstract), 107676−92, 107708, 107739−49, 107771−3, 107779, 107793, 107828, 107848−51, 107962, 108014−16, 108019−22, 108038−46, 108064−6, 108349−51, 108390−1, 108850−2, 109043−4, 109053, 109310, 109374−5, 109381−3

Practical Bayesian statistics; Cambridge, England, 21-24 July 1982, [March-June 1983] 105021 (introductory abstract),

Proton-antiproton collider physics; Rome, Italy, 12-14 Jan. 1983, *(Istituto Nazionale di Fisica Nucl.; Univ. Rome) C.Bacci, G.Salvini (editor/s),* [Geneva, Switzerland: CERN 1983] 105026 (introductory abstract), 105554, 105596−7, 105650, 105674−6, 105691−704, 106185−7

Quantitative surface analysis; Teddington, England, 24-25 Nov. 1981, [Aug. 1983] 105429−30, 108075, 108144, 108190, 109067, 109112−13, 109838

Radiation damage analysis for fusion reactors; St. Louis, MO, USA, 25-28 Oct. 1982, *(TMS-AIME/ASM Nucl. Metall. Committee; ASM Electr., Magnetic & Opt. Phenomena Activity)* [July 1983] 106162−6, 107750−2, 107762, 107775−6, 107786−7, 109634

Radioactive waste treatment and handling; Richland, WA, USA, 19-22 April 1982, *A.G.Blasewitz, J.M.Davis, M.R.Smith (editor/s),* [Richland, WA, USA: Battelle Press 1983] 105983−6068, 106076−7, 106179−80, 106182

Radiobiology; London, England, 18 Feb. 1983, [Sept. 1983] 105011 (introductory abstract),

Radionuclide metrology; Geel, Belgium, 16-17 May 1983, [1983] 105019 (introductory abstract), 105300−3, 106192, 106205−7, 106237−9, 106249, 106253−5

Relays, 1983; Stillwater, OK, USA, 26-27 April 1983, *(Oklahoma State Univ., Nat. Assoc. Relay Manuf)* [Elkhart, IN, USA: Nat. Assoc. Relay Manuf. 1983] 109516

Role and impact of space research in developing countries; Ottawa, Canada, 16 May-2 June 1982, *(COSPAR; Committee Sci. Tech. Developing Countries)* [1983] 105087 (introductory abstract),

Saturn, its rings, and satellites; Tucson, AZ, USA, 11-15 May 1982, [May 1983] 110968−9, 110971−5, 110977, 110979−80

Software for computer control; Madrid, Spain, 5-8 Oct. 1982, *(IFAC; IFIP) G.Ferrate, E.A.Puente (editor/s),* [Oxford, England: Pergamon 1983] 106112

Solar physics; Pasadena, CA, USA, 22-24 June 1983, [1983] 105013 (introductory abstract),

Space biology; Cologne, Germany, 9-11 March 1983, *(Eur. Low Gravity Res. Assoc.; ESA; German Aerospace Res. Establ)* [Noordwijk, Netherlands: ESA 1983] 109701, 110199−209

Surface imaging and analysis with high spatial resolution; Wickenburg Inn, AZ, USA, 12-15 Jan. 1983, [1983] 105024 (introductory abstract), 105440, 107501−2, 108145−50, 108192, 108239, 108521, 109074−5, 109114, 109807, 109966

Surface science; Tampere, Finland, 18-20 Aug. 1982, [1983] 107496, 108093, 108140, 108204, 108229−30, 108278−9, 108500, 108538, 109065−6, 109084, 109105−9, 109584, 109836

Total solar eclipse; Toronto, Ont., Canada, May 1980, [July 1983] 110771 (introductory abstract), 110572, 110743, 110772−9, 110866

Urban hydrology, hydraulics and sediment control; Lexington, KY, USA, 25-28 July 1983, *(Univ. Kentucky; Coll. Engng; et al) H.J.Sterling (editor/s),* [Lexington, KY, USA: OES Publications 1983] 105035 (introductory abstract),

Utilization of infrared technology; San Diego, CA, USA, 26-27 Aug. 1982, [1983] 105330, 105372−3, 106403, 109612, 109934−5, 110650, 110847, 110909

Wave propagation and remote sensing; Louvain-la-Neuve, Belgium, 9-15 June 1983, *(ESA; CEC)* [Paris, France: ESA 1983] 105033 (introductory abstract), 105312−13, 105358−60, 106669−81, 106978, 110613−40, 110734−9

Wescon '82; Anaheim, CA, USA, 14-16 Sept. 1982, [El Segundo, CA, USA: Electron. Conventions 1982] 105061−2

CORPORATE AUTHOR INDEX

Atomic Energy Canada Ltd., Chalk River, Ont.
  Characteristics of a thermal neutron source based on an intermediate energy proton accelerator, AECL-7839. 106200
  Conversion of smectite to illite in hydrothermal systems: A literature review, AECL-7792. 106147
  Diffusive transport of strontium-85 in sand-bentonite mixtures, AECL-6838. 105982
  Fuel cycles: A bibliography of AECL publications, AECL-6425 Rev.1. 105056
  Introduction to radiation protection principles, AECL-8057. 106178
  Kinetics of iodine and cesium reactions in the CANDU reactor primary heat transport system under accident conditions, AECL-7781. 106148
  Neutronic evaluations of activations in graphite-thorium assemblies, 14 MeV neutron sources: Comparisons with measurements, AECL-8060. 106171
  Purification of zirconium by electrotransport, AECL-8051. 109121
  Understanding the statistics of small risks, AECL-7541. 106149
Bur. Mines, Washington, DC, USA
  A digital instrumentation package for an improved torsion pendulum, RI-8774. 107087
Comm. European Communities, Luxembourg
  BENCHMARK. Reference data on post irradiation analysis of light water reactor fuel samples, EUR 7879 EN. 105980
  Case study, candidate technologies to relieve the European energy systems: Ireland, EUR 8035 EN. 109843
  Certification of a uranium metal reference material for chemical analyses, EUR 8349 EN. 105979
  Characterization of the pressure wave originating in the explosion of an extended heavy gas cloud: Critical analysis of the treatment of its propagation in air and interaction with obstacles, EUR 8482 EN. 106146
  Comportement en fatigue d'aciers a haute limite d'elasticite (Fatigue behaviour of steels with high elastic limit), EUR 8060 FR. 109515
  Critical confrontation of standard and more sophisticated methods for modelling the dispersion in air of heavy gas clouds; Evaluation and illustration of the intrinsic limitations of both categories, EUR 8423 EN. 109941
  Drawability of sheet material, EUR 6653 EN. 109434
  EURDYN: Computer programs for the nonlinear transient analysis of structures submitted to dynamic loading. EURDYN (Release 3): Users' manual, EUR 8357 EN. 105953
  Fatigue crack growth and fracture resistance of steels in high-pressure hydrogen environments, EUR 8191 EN. 109514
  Hydrogen safety manual, EUR 8396 EN. 109924
  Joint exercise to compare fatigue crack growth data obtained on type 304/316 stainless steel, EUR 8502 EN. 109512
  Mesure continue de l'epaisseur des revetements sur les toles (Continuous measurement of the thickness of coatings on metal sheets), EUR 8122 FR. 109603
  MORSE-E1, source and analysis routines to be used with the MORSE code, EUR 8420 EN. 105952
  MUP, CEC-DES, STRADE. Codes for uncertainty propagation, experimental design and stratified random sampling techniques, EUR 8244 EN. 105955
  Operational quantities for use in external radiation protection measurements. An investigation of concepts and principles, EUR 8346 EN. 106177
  Possible research program on a large scale nuclear pressure vessel, EUR 8221 EN. 106145
  Study of low-cycle fatigue behaviour of steels at high temperature, EUR 6497 EN. 109513
  Testing and evaluation of solidified high-level waste forms, EUR 8424 EN. 105981
  TPLOT: An interactive time plot system for transient structural problems, EUR 8391 EN. 105954
  Use of a heat transfer coefficient for describing the radiative exchange between water vapour and the bounding walls, EUR 8344 EN. 106106
Electr. Power Res. Inst., Palo Alto, CA, USA
  Fatigue performance of Ni-Cr-Fe alloy 600 under typical PWR steam generator conditions, EPRI-NP-2957. 106111
  Influence of base isolation on the seismic response of light secondary equipment, EPRI-NP-2919. 106150
  Investigation of phosphate-sludge interactions, EPRI-NP-2963. 106109
  Modeling of natural circulation phenomena in nuclear reactor cooling loops, EPRI-NP-2951. 105956
  Role of electrochemistry in causes and measurement of corrosion in PWR steam generators, EPRI-NP-2962. 106110
  Scale model tests of turbine missile containment by reinforced concrete, EPRI-NP-2747. 106152
  Study of dilute reagent decontamination for application in boiling water reactors, EPRI-NP-2960. 106107
  Testing of a natural rubber base isolation system by an explosively simulated earthquake, EPRI-NP-2917. 106151
  Thermal mixing in a rectangular geometry model of a cold leg with high-pressure injection and a downcomer, EPRI-NP-2924. 106108
Nat. Phys. Lab., Teddington, England
  Electromagnetic stirred mode cavities (SMCs), NPL-DES-75. 105340
UKAEA, Culham, Abingdon, Oxon., England
  Bundle divertor. A review of experimental results, CLM-R 235. 107451
  Predicted behaviour of the pumped limiter of INTOR, CLM-R 232. 107450
UKAEA, Risley, Lancs., England
  Auger spectra of lithium metal and 'oxidised lithium', ND-R-463(S). 109068
  Stress analysis of a rotating cylinder experiment to determine crack growth in thick section steel, ND-R-892(R). 109697

literature you
do not hold?

BOSTON SPA
Can help you

Over 54000 current periodicals available*

Most of the papers listed in INSPEC services are held at the British Library Lending Division (BLLD)

REQUESTS DEALT WITH IN 48 HOURS*

Write for further information to:

The Director General
The British Library Lending Division
Boston Spa
Wetherby
West Yorkshire LS23 7BQ
U.K.
Telephone 0937 843434

*Photocopies of papers are available for research or private study to organisations in the UK registered as users of the BLLD. Where individuals in the UK do not belong to an organisation registered with the BLLD they should apply via their public library. In case of difficulty please contact the BLLD.

All requests from outside the UK should be made via the BLLD Overseas Photocopy Service.

CUMULATIVE INDEXES

Cumulative indexes are available for *Physics Abstracts*, *Electrical & Electronics Abstracts* and *Computer & Control Abstracts*, for both authors and subjects. These cumulations generally cover a period of four years, with the exception of *Computer & Control Abstracts* where the initial volume covered the period 1966–68. The table below shows the prices and periods for the two types of cumulative index.

	PHYSICS ABSTRACTS		ELECTRICAL & ELECTRONICS ABSTRACTS		COMPUTER & CONTROL ABSTRACTS	
	Subject	Author	Subject	Author	Subject	Author
	£	£	£	£	£	£
1955-59	20	20	15	20	—	—
1960-64	40	17	20	12	—	—
1965-68	60	25	35	20	—	—
1969-72	—	—	72	64	48	30
1973-76	600	300	250	150	150	75
1977-80	770	450	380	250	250	120
1966-68	—	—	—	—	15

ORDERING PROCEDURE

THE AMERICAS

North (including Canada), Central and South

All orders from the above areas, and orders from members of Institute of Electrical and Electronics Engineers Inc. anywhere in the world, should be sent to Fulfillment Manager, Institute of Electrical & Electronics Engineers Inc., 445 Hoes Lane, Piscataway, N.J. 08854, USA. Telephone (201) 981 0060

日本のお客様にご案内申し上げます

日本国内に於けるINSPECの購入価格はすべて円建てとなっております　また刊行物はすべて航空便で配達されます　INSPEC刊行物の価格、その他についてのお問合わせは最寄の洋書取扱専門店または輸入総代理店㈱ユー・エス・エシアテック　カンパニー　〒105東京都港区新橋1　13　12、TEL 03（502）6471までご連絡ください

REMAINDER OF THE WORLD

All remaining subscriptions should be sent to INSPEC Marketing Department, P O Box 26, Hitchin, Herts SG5 7RS, England. Telephone Hitchin 53331, Telex 825962, Telegrams IEE G.

OTHER INSPEC SERVICES

SDI

(Selective Dissemination of Information.) This is a service individually tailored to the requirements and interests of the engineer or research worker. Details of information relevant to the interest profile of the individual subscriber are selected from the data being processed for the INSPEC database. Information is dispatched weekly on 150 mm × 100 mm (6″ × 4″) cards.

TOPICS

This is an SDI service based on standard profiles. There are over 70 subjects covering high-activity areas of research and development. This is an inexpensive card service designed to alert engineers and researchers to the availability of literature within their subject area.

MAGNETIC TAPES

Tapes containing all the information included in the INSPEC publications are issued twice monthly. They enable the larger research and development organisations to produce their own internal information and current-awareness services.

Physics Abstracts

15th November 1

Summary Classification

The full classification and contents are given at the front of the journal, followed by an **Alphabetical Index** to the subjects covered

00.00	**General**
01.00	Communication, Education, History and Philisophy
02.00	Mathematical Methods in Physics
03.00	Classical and Quantum Physics; Mechanics and Fields
04.00	Relativity and Gravitation
05.00	Statistical Physics and Thermodynamics
06.00	Measurement Science, General Laboratory Techniques, and Instrumentation Systems
07.00	Specific Instrumentation and Techniques of General Use in Physics
10.00	**The Physics of Elementary Particles and Fields**
11.00	General Theory of Fields and Particles
12.00	Specific Theories and Interaction Models; Particle Systematics
13.00	Specific Reactions and Phenomenology
14.00	Properties of Specific Particles and Resonances
20.00	**Nuclear Physics**
21.00	Nuclear Structure
23.00	Radioactivity and Electromagnetic Transitions
24.00	Nuclear Reactions and Scattering: General
25.00	Nuclear Reactions and Scattering: Specific Reactions
27.00	Properties of Specific Nuclei listed by Mass Ranges
28.00	Nuclear Engineering and Nuclear Power Studies
29.00	Experimental Methods and Instrumentation for Elementary-Particle and Nuclear Physics
30.00	**Atomic and Molecular Physics**
31.00	Theory of Atoms and Molecules
32.00	Atomic Spectra and Interactions with Photons
33.00	Molecular Spectra and Interactions with Photons
34.00	Atomic and Molecular Collision Processes and Interactions
35.00	Properties of Atoms and Molecules; Instruments and Techniques
36.00	Studies of Special Atoms and Molecules
40.00	**Classical Areas of Phenomenology**
41.00	Electricity and Magnetism; Fields and Charged Particles
42.00	Optics
43.00	Acoustics
44.00	Heat Flow, Thermal and Thermodynamic Processes
46.00	Mechanics, Elasticity, Rheology
47.00	Fluid Dynamics
50.00	**Fluids, Plasmas and Electric Discharges**
51.00	Kinetic and Transport Theory of Fluids; Physical Properties of Gases
52.00	The Physics of Plasmas and Electric Discharges
60.00	**Condensed Matter: Structure, Thermal and Mechanical Properties**
61.00	Structure of Liquids and Solids; Crystallography
62.00	Mechanical and Acoustic Properties of Condensed Matter
63.00	Lattice Dynamics and Crystal Statistics
64.00	Equations of State, Phase Equilibria, and Phase Transitions
65.00	Thermal Properties of Condensed Matter
66.00	Transport Properties of Condensed Matter (Nonelectronic)
67.00	Quantum Fluids and Solids; Liquid and Solid Helium
68.00	Surfaces and Interfaces; Thin Films and Whiskers
70.00	**Condensed Matter: Electronic Structure, Electrical, Magnetic, and Optical Properties**
71.00	Electron States
72.00	Electronic Transport in Condensed Matter
73.00	Electronic Structure and Electrical Properties of Surfaces, Interfaces, and Thin Films
74.00	Superconductivity
75.00	Magnetic Properties and Materials
76.00	Magnetic Resonances and Relaxation in Condensed Matter; Mossbauer Effect
77.00	Dielectric Properties and Materials
78.00	Optical Properties and Condensed Matter Spectroscopy and other Interactions of Matter with Particles and Radiation
79.00	Electron and Ion Emission by Liquids and Solids; Impact Phenomena
80.00	**Cross-Disciplinary Physics and Related Areas of Science and Technology**
81.00	Materials Science
82.00	Physical Chemistry
86.00	Energy Research and Environmental Science
87.00	Biophysics, Medical Physics, and Biomedical Engineering
90.00	**Geophysics, Astronomy and Astrophysics**
91.00	Solid Earth Geophysics
92.00	Hydrospheric and Atmospheric Geophysics
93.00	Geophysical Observations, Instrumentation, and Techniques
94.00	Aeronomy and Space Physics
95.00	Fundamental Astronomy and Astrophysics, Instrumentation and Techniques and Astronomical Observations
96.00	Solar System
97.00	Stars
98.00	Stellar Systems; Galactic and Extragalactic Objects and Systems; The Universe
